Abstract

The following discussion is concerned with certain forms of poor practice in academic publishing that give rise to “academic urban legends”. It suggests that rather than simply consider phenomena such as poor citation practices and circular reporting as mistakes, misunderstandings, and evidence of lack of rigour, we might also read them as evidence of a particular kind of creativity – for which misunderstandings, assumptions and failures of diligence are mechanisms by which potentially influential ideas manifest. Reflecting particularly on a critique of the debate around pharmaceutical cognitive enhancement and its use by university staff and students, the following will argue that investigators within these disciplines are themselves implicated as potential subjects. Alongside reflections from science fiction studies that offers insights into the experiential dimension of reading and misreading, this paper offers some insights regarding how we might think of mistakes and misunderstandings as a form of bootstrapping and a source of creativity in scientific and technological development.
**Academic urban legends**

In his paper *Academic Urban Legends*, Ole Bjørn Rekdal (2014a) reconstructed the birth of the widely held but misplaced belief that ‘spinach is an excellent source of iron’ (p.639). Ironically, through the poor citation practices of those who commented on it, the story about spinach, often used as an example of academic carelessness, became attached to another academic urban legend, which blamed the mistake regarding spinach’s dietary attributes on the misprinting of a measurement of iron content with a misplaced decimal point. Tracing back through the nested citations that gave rise to this second story Rekdal (2014a) showed that it too, is ungrounded. Many of the authors who mistakenly used the example of spinach in this way never went back to consult the original source, with the result that a claim that was itself unsubstantiated, was also consistently reported inaccurately. A damning pattern of citation errors in work that was intended to debunk myths in science and medicine but instead perpetuated them was the result.

Citation plagiarism - in which a secondary citation is presented as a primary one without consulting the original source, was the main culprit in Rekdal’s analysis (2014, p.639) As he pointed out, for academic writers who want to reuse an idea or phrasing, the temptation is to make use of references reported in other texts in this way. If the preceeding author has reported the content of the source with honesty and accuracy, this kind of omission is undetectable. Unreliable sources, and citation that misrepresents and solidifies tentative or faulty evidence however, contribute to the generation of academic urban legends.

Despite the moral and practical implications of having the wrong facts before us, in the case of academic writing the selection of evidence to build an argument is also engaged with the considerations of how to get an argument where it is going. Whether careless, lazy, or outright
dishonest, the examples that Rekdal examined in his work are troubling; both given the effects of a misapprehension with the scale and influence of the myth about spinach, and how apparently endemic this type of inaccuracy appears to be (Rekdal, 2014a; 2014b). However, as the following discussion will suggest, apart from as failure, the academic urban legend can also be read in another way - as evidence of a particular kind of creativity – for which misunderstandings, assumptions and failures of diligence are mechanisms by which potentially influential ideas manifest.

The self-referential debate about neuro-enhancement technologies

Debates about neuro-enhancement technologies are another discourse that garnered criticism. An example is Hazem Zhony’s (2015) analysis of the discussion of ‘pharmaceutical cognitive enhancement’ (PCE), PCE is the off-prescription use of drugs such as Adderall and Ritalin for performance enhancement that has been allegedly on the rise in workplaces, schools and universities (the discussion centres around the United States). Zhony argued that while recently the subject of intense discussion, the nature, novelty, and prevalence of PCE has been consistently overstated. In addition to a number of conceptual problems, technologies indicated by the novel terms “cognitive- and neuro-enhancement” (p. 264) are neither conceptually or technologically new;¹ and the concept of neuroenhancement itself is a misnomer. Zhony argued that there is good evidence that drugs associated with cognitive enhancement only generate experiences of enhanced cognitive function - improving mood and feeling, but not actual

¹ Adderall for example, is a mixture of amphetamines. Although at this juncture Tom Wolfe would probably point out that the widespread practices of prescribing amphetamines to children may be new, despite the fact that he first came across their use in the 1960 (Wolfe, 1997). For a history of the relationship of drug to network technologies see (Power, 2013).
performance. Cognition – when separated from mood and attention – is a problematic category (p.263-4).

Similar with Rekdal’s discussion of citation plagiarism, Zhony pointed out that the discourse around PCE shows evidence of “circular reporting, whereby the media references academic papers and academic papers reference the media” (p. 265). In this back and forth between the academic literature and the media – which regularly reports on PCE and other forms of cognitive enhancement such as ‘nootropics’, the to interrogate the quality of citations has led to the perception that PCE is effective and widespread in use.

While PCE may be partly fiction, the debate around it remains productive in a number of ways. For commentators, particularly in disciplines such as neuroethics, the growth of the PCE legend has offered an argument for discussions about the politics of enhancement legality and decriminalisation, workplace pressure, education, and neoliberalism (Wiegel et. al, 2016; Sampson, 2016). The dialogue, for better or worse, is one that moves between academic disciplines, and the popular press where commentators attempt to open, and perhaps feed the debate. Petrounin’s (2014) article “European Students’ Use of ‘Smart Drugs’ Is Said to Rise” in the New York Times, cites an interview with an academic who despite having ‘no longitudinal data’, has the ‘impression from discussions with students over the last years that consumption has likely increased’ (Savulescu, 2015). The exciting and troubling prospect of widespread PNE becomes a hook, or perhaps a wedge, a way to accesses and evidences other, more occult and harder to articulate problems around self-determination, emerging technology, and the nature of knowledge-work. Another feature of this debate is the way in which the regularity with which PCE and similar technologies are mentioned popularizes and spreads the idea that they are necessary and acceptable. Inaccurate and overblown it may be, but the idea of neuro-
enhancement is an idea with substantial weight, and as a technological imaginary (Punt, 2000) encapsulates a popular model for a technology that holds sufficient weight to pick up its own momentum.\(^2\)

**Cognitive innovation, looping effects, and bootstrapping.**

Central to the integrative definition of ‘cognitive innovation’ proposed by CogNovo PIs was been the idea that it is a process by which an individual, or a society, engages in ‘constructing and adapting the self’ (Gummerum and Denham, 2014, p. 586). Taking this as a model of cognitive ‘bootstrapping’ they refer to a recursive ‘creativity function’, the results of which are creative products that may be seen as the results of individual self-adjustment and self-reflexive perception (Denham & Punt, 2017, p. 1). With its focus on recursive processes, this definition of cognitive innovation can be seen to refer to the cybernetic potential of the mind at work on itself, both at a neural and – through representation – cultural level.

While individual cognitive innovation is self-reflexive, if not self-aware, on a cultural level it might be argued that the cognitive sciences and discourses that surround them are a source of novel ideas about the mind and self that might be incorporated into working models of exploration. The idea that the language, models, and discourses of the human sciences influence the way in which people understand themselves is a mainstay of academic work that seeks to them from historical and cultural perspectives. Projects of categorization, diagnostic and managerial in the human and social sciences influence how people think about themselves and one other, with the curious effect that they become ‘looping kinds’ (Hacking, 1995, p. 352-355).

\(^2\) Atkinson’s. *Delete: a Design History of Computer Vapourware*, 2013, offers complimentary examples of how the computing industry has produced ‘vapourware’ products that are in some cases never intended to reach production, but instead provide the public with misconceptions about technological capabilities or near-to-market products.
Michael Pettit has pointed out that “few have greater confidence in psychology’s ability to mold subjectivity than its critics” (2015, p.146): the principle of looping kinds is so rarely questioned that it has become a truism. He argues that current work to historicize psychology tends all too easily to anticipate a one-directional flow of influence between the sciences and the subject. He makes a number of suggestions about what is missing from accounts of ‘the loop’. Building on an awareness that “subjectivity is neither something authentic and interior that psychology documents nor is it something imposed from outside” (p. 155), approaches might incorporate models of cognition and affect; or models of culture. These recognize the agency of audiences and their role in interpreting and making use of the way in which they are represented; “the social life of psychological science is simultaneously a set of stories about the subject’s augmentation, exploitation, cooptation, appropriation, defiance, incredulity, and boredom”(p. 155).

Pettit’s critique, and his suggestion that we might be more “attentive to […] the materiality of the circuits through which psychology travels” (p. 155) also suggests something might be gained from further exchange between critical history of psychology and media historical or media archaeological work that considers people not as subjects, but as audiences. While some of this work takes its objects of study to be the development of specific media forms, for the most part accounts of cognition and affect, and the audience as actively engaged in the interpretation, reception and development of media forms and content, are fundamental concerns; media, such as the academic texts and media reports discussed above, are material and cultural expressions of creativity (Punt, 2000; Pepperell and Punt, 2003). In The View from the Bridge, Denham and Punt (2017) elucidate this position with regards to the development of the cinema as a cognitive apparatus. They draw on Gustav Metz to argue that the cinema is a “is a
technological experience in which the viewer engages with their perception in action” (p. 2). We might imagine that in the case of media which represents ideas from the psychological or cognitive sciences, that this self-reflexivity may become even more pronounced. Indeed, Marcia Holmes, in a paper exploring the representation of brain-washing technologies in cinema, argues that these narratives, delivered by a cinematic apparatus comparable to the represented technology in the film produce a particular, and very active subject position, that of the “cybernetic spectator” – “a subject who scrutinises how media and other demands on her sensory perception can affect consciousness, and seeks to consciously participate in the mental conditioning and guide its effects” (Holmes, 2017, p. 3).

Bearing in mind this self-referential attention to the meaning and content of experience, within a narrative that stresses the plasticity and potential manipulability of the subject, we might reflect on the fact that in certain cases, as researchers, academics and educators, the subjects of the PCE discussion are broadly same community who investigate it. As Holmes invocation of cybernetics stresses, much as the invocation of ‘bootstrapping’ (Punt and Denham, 2016, p. 184), the looping effects are in themselves generative, and hence academic mistakes and misunderstandings, we might speculate that they are evidence of cultural level cognitive innovation. In this, the media offers an expression as well as ‘scaffolding’ (Clark, 2015, p. 18) for cognitive innovation as much as cultural creativity.

**Academic writing as sf – and using sf to discuss it.**

Since the late 80s and 90s the invention of novel terms signifying new technological and conceptual developments have offered a currency of bi-directional exchange between techno-
scientific research, culture and science fiction (sf), there is a lot to be recommended here – Ronay’s earlier work on Haraway As Istivan Csicsery-Ronay (2008).

Csicsery-Ronay’s in depth analysis of the nature and affordances of ‘fictive neology’ (p.13-46) is instructive as to how we might begin thinking about the creative and aesthetic aspects of discourses that have cultural intersections with sf, Neologisms are generated in a variety of ways that include shifts in meaning, lengthening, shortening, and compounding terms. points out, it is only when certain aspects of scientific knowledge become accessible to the public through journalism and science communication initiatives, that they are ubiquitous enough to be incorporated into writing practices, as academic, journalistic, and fictional discourses intermingle. The practice of ‘neologogenesis’, the creation of new terms, is one that communicates the ‘linguistic power’ (p. 14) of the new word’s users.

In sf, the very existence of new words in the fictional world prompt the reader to consider the events and conditions that have made them necessary. As Csiscery-Ronay suggests, drawing on Samuel Delaney’s work, in a text where many, if not all of the words are familiar, we assume that the world described in the text is identical to the one we already know (p.22). When a neologism appears in the text, we must account for what is different about that world that has led to the word coming into existence, and indeed use. The loglo of Neal Stephenson’s Snow Crash (1992: 7) – the unbroken lights of fast food franchises, motels and nation states that line the freeways of U.S West coast – indicates a specific feature of the landscape so ubiquitous it requires its own term. but within the account he offers is a discussion of the kind of experience that engagement with novel terminology evokes, that points this discussion towards a consideration of how the academic texts discussed above dealt with. The way they function for the readers, writers and thinkers who make use of them; and how neologisms create a certain
type of reading experience.

When do readers do this work of interpreting? While novel words prompt imaginative invention, but they might also be dealt with by being ignored, or at least overlooked. A feature of perceptual creativity and bootstrapping, may be a development of the ability to overlook or ignore one’s lack of understanding or familiarity with a term. Rekdal’s (2014) reminder that striving to use primary sources is a ‘basic academic principle’ (p.744) is correct, but still, secondary citation, offers a space for ‘boostrapping’. Likewise the ‘feverish linguistic atmosphere’ (Csicsery-Ronay, p. 26) of genres such as cyberpunk fiction might offer cognitive training grounds for dealing with unresolvable levels of novelty and ambiguity, whether for the apparent dislocations of contemporary techno-culture, or perhaps working in a transdisciplinary research environments where ambiguity is often criticized, but may have its own benefits.

Despite the conflicting variety of reasons that individuals are interested in the discussion of PCE, the ways in which the discussion has been generated, enabled and distorted, can be seen as a productive cultural function of the mind’s interest in itself, the potential misunderstandings about PCE that it entails don’t mean that it is necessary to undermine the productivity of the discourse, if we consider how they reflect potentials rather than facts. Circular reporting and academic urban legends fit alongside the creative shifting of neologism. As different features of writing practices, they offer ways for the bootstrapping processes of self-adjustment to take place within and at the fringes of research spaces. They suggest that people, including scientists – on individual and social levels – may be thought of as ‘cybernetic investigators’, whose failings

---

4 This observation would also be supported by the similar discussions around direct current stimulation (DCS) technologies, which involve the application of electrical current to the head or brain, equally for therapeutic purposes/neuroscientific experimentation and (apparently) increasingly used for performance enhancement (Wexler, 2016).
may sometimes have their own value.

Acknowledgments

I would like to thank Diego Maranan and Witold Wachowski for their very useful responses to on the earlier stages of this paper and Diego for patient and perceptive feedback during the revision process.
