1 Analytical study on wave power extraction from a hybrid wave

2 energy converter

3 Abstract: In this paper, a hybrid wave energy converter (WEC) is proposed, consisting of a fixed

4 inverted flume with long length and a bottom hole, and a long floating cube hinged with the

5 flume. The inverted flume and the long floating cube works as an oscillating water column

6 (OWC) and a rotational float, respectively, to capture power from incident waves. To study the

7 performance of this hybrid WEC, analytical solution of the wave diffraction/radiation problems,

8 considering the hydrodynamic interaction between the OWC and the float, is derived based on

9 linear potential flow theory and eigen-function expansion matching method in the two-

10 dimensional Cartesian coordinate systems. The corresponding hydrodynamic coefficients, such as

11 wave excitation forces, added mass and wave radiation damping, are also obtained, which can be

12 further used in evaluation of the maximum theoretical power absorption of the hybrid WEC.

13 Results are compared with a parallel study of an isolated OWC and an isolated float.

14 Additionally, analytical study on power capture capability of the device for various geometrical

15 parameters is then carried out.

16 Keywords: Linear potential flow theory, Analytical model, Wave power extraction, Oscillating

17 Water Column, Hinged float

18 **1. Introduction**

Oscillating water column (OWC) has been recognized as one of the most effective concepts of
wave energy conversion, which mainly consists of a partially submerged rigid chamber and
exploits wave power by driving an air turbine using the oscillating motion of the inner free water
surface (Heath, 2012; Malara and Arena, 2013; Deng et al., 2014; He and Huang, 2017; Chen et

al., 2017). To understand and improve wave power extraction by OWC devices, experimental,

numerical, and analytical methods have been widely employed and many different design of
 OWC devices have been proposed as well.

26 Experimental tests present a straightforward way to study the performance of OWC devices. For

the case where the OWC is very long in the horizontal co-ordinate compared to the wave length,wave diffraction and radiation from the OWC can be concerned with a two-dimensional problem.

wave diffraction and radiation from the OWC can be concerned with a two-dimensional proble
 Sarmento (1992) carried out wave flume experiments on two-dimensional OWC devices and

found a good agreement between the experimental data and the prediction values from linear

theory. Morris-Thomas et al. (2007) experimental data and the prediction values from linear theory. Morris-Thomas et al. (2007) experimentally studied a shore based oscillating OWC

device, and found that the increase in front wall submergence reduced the power capture

efficiency in short waves. He et al. (2013, 2017) considered the integration of OWC devices with

a floating breakwater, which was experimentally found to be a promising way to widen the

frequency range for power extraction. Due to the constraints of laboratory facilities, funding and

time in conducting experimental studies of OWC devices, numerical and analytical methods were
 preferred by many researchers.

Numerical studies on OWC devices are commonly performed by using BEM (Boundary Element

39 Method) models and RANS (Reynolds-Averaged Navier-Stokes equations) models, which are

40 based on potential flow theory and viscous fluid theory, respectively. Sheng et al. (2014) used an

41 imaginary "piston" to replace part of the water at the internal water surface in the OWC chamber

42 and solved the hydrodynamic problems from the device itself and the imaginary "piston" by using

43 a commercial BEM model. Appropriate representation of the "imaginary" piston was found very

1 important, when the hydrodynamic parameters were to be transformed from frequency-domain to

2 time domain for a further analysis. Rezanejad et al. (2013, 2015) adopted BEM method to analyse

3 the efficiency of a two-dimensional nearshore multiple OWC devices placed over flat bottom and

4 stepped bottom, respectively. Ning et al. (2015, 2017) applied a fully nonlinear numerical wave

5 flume based on higher-order BEM in simulating of both one-chamber and dual-chamber OWC

6 devices. Numerical results indicated that the surface elevations in the two sub-chambers are

7 strongly dependent on the wave conditions. Compared with BEM models, the RANS models are

capable to handle problems with very strong nonlinearity induced by turbulence, viscous, vortex
shedding and wave breaking. Elhanafi et al. (2016, 2017) used a fully nonlinear 2D RANS model

to carry out analysis of onshore and offshore OWC devices, respectively. Frequency response of

11 the overall hydrodynamic efficiency showed a single-peaked curve and it was revealed that

12 increase of the submergence of lips was beneficial to the energy extraction in long waves,

13 whereas went against power absorption for short waves. Other numerical investigations on OWC

14 devices with implementation of RANS models can be found in Zhang et al. (2012), López et al.

15 (2014, 2016), Iturrioz et al. (2015). However, as the RANS model utilized in the above-

16 mentioned numerical simulations normally requires a much more computational power, its

17 employment is limited to a certain extent in some ways.

18 For the OWCs in regular shapes, the analytical method, which is generally based on potential

flow theory and eigen-function expansions, can be a good alternative option, especially in their
pre-feasibility study and even their feasibility study, and can be used to provide insights and
important information rapidly at relatively low costs.

As early as 1980s, Evans (1982) presented theoretical results of wave-power absorption by a two-

dimensional system of uniform oscillatory surface pressure distributions based on the linearized
 hydrodynamic theory. Later, Falnes and McIver (1985) applied analytical method to study the

25 power absorption by an OWC, which is composed of two vertical barriers with unequal length,

oscillating in the surge mode. It was shown that all of the incident wave power can be captured by
the system with optimum values of the complex oscillation amplitudes. Sarmento and Falcão

28 (1985) developed an analytical analysis for an OWC device in which the immersed part of the

OWC was assumed of shallow draught. Evans and Porter (1995) described an accurate model
 using matched eigen-function expansions and a Galerkin method to compute the hydrodynamic

31 coefficients associated with an OWC device consisting of a thin vertical surface-piercing barrier 32 next to a vertical wall. This method has been widely used in solving the hydrodynamic problems

of the OWC based on thin barrier assumption. It was found that the OWC with a larger chamber
 width had a smaller wave frequency at which resonance occurs. Rezanejad et al. (2013) studied

35 the performance of a dual-chamber OWC device which consists of two vertical thin barriers in

36 front of a vertical wall. It was revealed that the draft of the outside chamber was a dominant

parameter determining the basic resonance frequency of power extraction. Later, the dual chamber OWC with vertical thin barriers placed over stepped bottom was also analysed

(Rezanejad et al., 2015). Noad and Porter (2017) considered a simplified model of a shallow-

40 draughted multiple-chamber OWC which is comprised of a series of open bottomed chambers

each enclosing an internal free surface. It was identified that variations in chamber sizing wereadvantageous, with larger chambers positioned to the aft, not only dividing the power capture

43 more evenly between the chambers, but also leading to a broader-banded response. As another

44 development of the simple OWC, the U-OWC device utilizing a small vertical U-duct for

45 connecting the air pocket to the open wave field was introduced and its performance was 46 analytically investigated by Recent (2007) and Malars and Arms (2012). While the constitu-

46 analytically investigated by Boccotti (2007) and Malara and Arena (2013). While due to either
47 "thin barrier" or "shallow draught barrier" assumptions, the analytical models proposed so far are

48 not valid in dealing with a more common situation, where the thickness and draught of the OWC

49 chamber cannot be ignored. Although Zheng and Zhang (2016) have recently developed an

50 analytical model for diffraction and radiation problems of multiple floats, in which any two

51 adjacent floats might be seen as the fore and aft walls of OWC with arbitrary thickness, the

1 radiation problem due to pressure oscillation inside the OWC chamber has not been taken into

- 2 account.
- 3 This paper extends the previously mentioned traditional offshore OWC concept, discussed by
- 4 Elhanafi et al. (2017), by considering a long oscillating floating cube hinged onto the OWC. The
- 5 aim is to enhance the performance of overall wave energy absorption. Apart from harnessing
- 6 power by the air turbine at the top of the OWC, rotation of the float (the long oscillating floating
- 7 cube) relative to the OWC can also be adopted to drive a cylinder installed between the OWC and
- 8 float, extracting wave power. Therefore, the device might be named as a hybrid wave energy
- 9 converter (WEC). On the one hand, due to the physical connection of the oscillating float onto the
- 10 OWC, no mooring system is required for the float and the costs of construction could be reduced.
- 11 On the other hand, it is believed that, with an optimized dimension, power extraction of the
- hybrid WEC can be obviously improved for a large range of wave frequencies due to thehydrodynamic interaction between the OWC and oscillating float. To study the hydrodynamic
- 14 performance of the hybrid WEC, the previously mentioned analytical model for the diffraction
- and radiation problem from multiple floats, discussed by Zheng and Zhang (2016) is extended by
- 16 considering the radiation due to pressure oscillation between two adjacent floats, and then
- 17 employed to carry out a geometric parametric study of the hybrid WEC. Results are compared
- 18 with a parallel study of an isolated OWC and an isolated float.
- 19 The rest of the paper is organized as follows. Section 2 describes the analytical model used in the
- 20 hydrodynamic simulations. Section 3 presents the validation of the analytical model. Results and
- 21 discussions are provided in Section 4. Conclusions are summarized in Section 5.
- 22

23 2. Analytical model

24 2.1. Problem description

The hybrid WEC proposed is mainly composed of a fixed OWC chamber and a float, as shown in Fig. 1. The float is connected to the fore wall of the OWC through a rigid arm. As ocean waves pass through the hybrid WEC, the OWC can be used to drive an air turbine and a motor installed at the top of the OWC chamber to capture wave power. Additionally, the wave-induced rotation of the float around the hinge can be employed to drive a hydraulic cylinder installed between the

rigid arm and the OWC to exploit wave power as well.

31 It is assumed that the monochromatic incident waves of small amplitude A and frequency ω propagate perpendicularly to the WEC and the length of the hybrid WEC along the crest line of 32 33 these incident waves is much larger than wave length. Therefore, wave diffraction/radiation 34 problems of this WEC can be treated as two-dimensional ones. As given in Fig. 1, a Cartesian 35 coordinate (x, z) system with its original point O located at the point of intersection of the mean 36 water surface and the front wall of the float is used to formulate the hydrodynamic problem of the 37 hybrid WEC, in which x and z denote the incident wave propagation and the upward direction, 38 respectively. The width of the float, the thickness of the fore wall and aft wall of OWC chamber 39 are denoted as a_1, a_2 and a_3 , respectively. The draft of the float, the submergence of the fore wall 40 and aft wall of OWC chamber are denoted as d_1 , d_2 and d_3 , respectively. a represents the water 41 column width inside the OWC chamber; d denotes the height of the hinge relative to the mean 42 water surface; D represents the distance between the float center and the fore wall of OWC. The 43 water area is considered with a constant depth of h. As shown in Fig.1, if we choose the hinge

- 1 point as a reference point of the float motion, the floater has only one degree of freedom, i.e. pitch
- 2 rotation relative to the hinge point. In such situation, the excitation pitch moment and the
- 3 hydrodynamic coefficients in rotation mode of the float are strongly dependent on the height of
- 4 the hinge relative to the mean water surface, i.e. d. In this paper, the center of gravity of the float
- 5 (x_0, z_0) is used as the reference point to calculate the motion response of the float. Hence surge,
- heave and pitch modes should all be considered in solving wave diffraction and radiation 6
- 7 problems. The mechanical relation between the surge/heave and pitch modes induced by the
- 8 hinge constraint can be further taken into account in evaluating motion response of the WEC
- 9 without resolving hydrodynamic problem for different d.
- 10

12

Fig. 1. Definition sketch of the hybrid WEC

13 In common with the assumptions that have been adopted by Zheng and Zhang (2016), in this 14 paper, the fluid is considered isotropic and incompressible inviscid, the time-harmonic flow is 15

irrotational, and the deformation of both float and OWC chamber are neglected.

16 With the employment of linear potential flow theory, the fluid motion can be expressed by the velocity potential $\varphi = \operatorname{Re}\left[\Phi(x, z) e^{-i\omega t}\right]$, where Φ is a complex spatial velocity potential 17 18 satisfying the Laplace equation; i is the imaginary unit and t is the time.

19 Φ can be decomposed into an incident wave spatial potential $\Phi_{\rm I}$, a diffracted wave spatial

20 potential $\Phi_{\rm D}$ and four radiated wave spatial potential $\Phi_{\rm R}^{(L)}$:

21
$$\Phi = \Phi_{\rm I} + \Phi_{\rm D} + \sum_{L=1}^{3} \dot{A}_{L} \Phi_{\rm R}^{(L)} + p \Phi_{\rm R}^{(4)}, \qquad (1)$$

22 where \dot{A}_L is the complex amplitude of the float velocity oscillation in mode L (L=1, 2, 3, which 23 represent surge, heave and pitch, respectively); $\Phi_{R}^{(L)}(L=1, 2, 3)$ is the spatial velocity potential 24 due to unit amplitude velocity oscillation of the float in mode L; p is the complex air pressure

1 amplitude inside the OWC chamber; $\Phi_{R}^{(4)}$ is the spatial velocity potential due to unit air pressure 2 oscillation inside the OWC chamber.

³ Expression of $\Phi_{\rm I}$, the dominate equation and the boundary conditions that $\Phi_{\rm D}$ and $\Phi_{\rm R}^{(L)}$ (L=1, 2,

4 3) should satisfy can all be found in our previous paper (Zheng and Zhang, 2016). Compared with 5 $\Phi_{\rm R}^{(L)}(L=1, 2, 3)$, due to the existence of air pressure oscillation inside the OWC chamber, the only 6 different boundary condition for $\Phi_{\rm R}^{(4)}$ happens on the free water surface in the OWC chamber, 7 where $\Phi_{\rm R}^{(4)}$ should satisfy

(2)

8
$$\frac{\partial \Phi_{\rm R}^{(4)}}{\partial z} - \frac{\omega^2}{g} \Phi_{\rm R}^{(4)} = \frac{{\rm i}\,\omega}{\rho g},$$

⁹ in which ρ is the water density and g is the gravity acceleration.

10 2.2. Formulation of the wave diffraction/radiation problem

11 To solve the wave diffraction and radiation problems, the fluid domain is divided into 7

subdomains denoted as Ω_j (*j*=1, 2, ..., 7) as shown in Fig. 2.

13 14

Fig. 2 Sketch of the subdomains of water domain

15 Utilizing the method of separation of variables, the analytical expressions for unknown

16 diffracted/radiated spatial potential in each subdomain can be obtained as follows (Zheng and

17 Zhang, 2016; Falnes, 2002):

18 Wave diffraction problem

In regions 1, 2m+1, 2m and 7, the diffracted potentials may be expressed, respectively, as follows:

21
$$\Phi_{\mathrm{D},1} = \sum_{j=1}^{\infty} A_{\mathrm{I},j}^{\mathrm{D}} \mathrm{e}^{\lambda_j x} Z_j(z) \quad \text{in } \Omega_1.$$
 (3)

1 For *m*=1, 2,

2

$$\Phi_{D,2m+1} = \sum_{j=1}^{\infty} \left(A_{2m+1,j}^{D} e^{\lambda_{j} x} + B_{2m+1,j}^{D} e^{-\lambda_{j} x} \right) Z_{j}(z) \text{ in } \Omega_{2m+1}.$$
(4)

3 For *m*=1, 2, 3,

4
$$\Phi_{D,2m} = -\Phi_{I} + A_{2m,1}^{D} x + B_{2m,1}^{D} + \sum_{j=2}^{\infty} \left(A_{2m,j}^{D} e^{\beta_{m,j} x} + B_{2m,j}^{D} e^{-\beta_{m,j} x} \right) \cos\left[\beta_{m,j} \left(z + h \right) \right] \text{ in } \Omega_{2m} . \tag{5}$$

5
$$\Phi_{D,7} = \sum_{j=1}^{\infty} A_{7,j}^{D} e^{-\lambda_j x} Z_j(z)$$
 in Ω_7 . (6)

A^D_{1,j}, A^D_{2m+1,j}, B^D_{2m+1,j}, A^D_{2m,j}, B^D_{2m,j} and A^D_{7,j} as given in Eqs. (3)~(6) are unknown coefficients to
be determined; Eq. (4) represents a general wave solution for the velocity potential in a uniform
fluid of constant depth (Falnes, 2002); β_{m,j} and λ_j are the eigenvalues of the *j*-th wave modes in
subdomain 2m, and subdomains 1 and 2, respectively, given as:

10
$$\lambda_1 = -\mathbf{i}k , \ j=1, \tag{7}$$

11
$$\omega^2 = -\lambda_j g \tan(\lambda_j h), \ j=2, 3, 4, \dots,$$
(8)

12
$$\beta_{m,j} = \frac{(j-1)\pi}{h-d_m}, \ j=2, 3, 4, \dots,$$
(9)

13
$$Z_{j}(z) = N_{j}^{-0.5} \cos\left[\lambda_{j}(h+z)\right], \quad N_{j} = \frac{1}{2}\left[1 + \frac{\sin\left(2\lambda_{j}h\right)}{2\lambda_{j}h}\right], \quad (10)$$

14 in which k is the wave number satisfying $\omega^2 = gk \tanh(kh)$.

15 Wave radiation problem

16 In regions 1, 2m+1, 2m and 7, the radiated potentials can be expressed, respectively, as follows:

17
$$\Phi_{\mathrm{R},1}^{(L)} = \sum_{j=1}^{\infty} A_{1,j}^{(L)} \mathrm{e}^{\lambda_j x} Z_j(z) \text{ in } \Omega_1.$$
 (11)

18 For *m*=1,2,

19
$$\Phi_{\mathrm{R},2m+1}^{(L)} = \sum_{j=1}^{\infty} \left(A_{2m+1,j}^{(L)} \mathrm{e}^{\lambda_{j}x} + B_{2m+1,j}^{(L)} \mathrm{e}^{-\lambda_{j}x} \right) Z_{j}(z) - \frac{\mathrm{i}\delta_{L,4}\delta_{m,2}}{\rho\omega} \quad \text{in } \Omega_{2m+1}.$$
(12)

20 For *m*=1, 2, 3,

1
$$\Phi_{\mathrm{R},2m}^{(L)} = \Phi_{\mathrm{R},2m}^{\mathrm{p},L} + A_{2m,1}^{(L)}x + B_{2m,1}^{(L)} + \sum_{j=2}^{\infty} \left(A_{2m,j}^{(L)} \mathrm{e}^{\beta_{m,j}x} + B_{2m,j}^{(L)} \mathrm{e}^{-\beta_{m,j}x} \right) \cos \left[\beta_{m,j} \left(z + h \right) \right] \text{ in } \Omega_{2m} . (13)$$

$$\Phi_{\rm R,7}^{(L)} = \sum_{j=1}^{\infty} A_{7,j}^{(L)} e^{-\lambda_j x} Z_j(z) \text{ in } \Omega_7.$$
(14)

3 In Eqs.(7)~(10), $A_{1,j}^{(L)}$, $A_{2m+1,j}^{(L)}$, $B_{2m+1,j}^{(L)}$, $B_{2m,j}^{(L)}$, $B_{2m,j}^{(L)}$ and $A_{7,j}^{(L)}$ are unknown coefficients to be 4 determined; $\delta_{i,j}$ denotes the Kronecker delta, and $\Phi_{R,2m}^{p,L}$ represents a special solution of $\Phi_{R,2m}^{(L)}$ 5 expressed as

6
$$\Phi_{\mathrm{R},2m}^{\mathrm{p},L} = \delta_{m,1} \left[\frac{\left(z+h\right)^2 - x^2}{2\left(h-d_m\right)} \delta_{2,L} - \frac{\left(z+h\right)^2 \left(x-x_0\right) - \frac{1}{3} \left(x-x_0\right)^3}{2\left(h-d_m\right)} \delta_{3,L} \right].$$
(15)

7 2.3. Solution to diffracted/radiated potentials

2

8 At either the interface between two adjacent subdomains or the fluid-structure interface, the 9 motions of the structures and fluids is fully coupled by pressures or/and velocities normal to the 10 interfaces. The continuity conditions at these interfaces for $\Phi_{\rm D}$ has been previously given in 11 Zheng and Zhang (2016). To shorten the paper length, here only the continuity conditions for 12 $\Phi_{\rm R}^{(L)}(L=1, 2, 3, 4)$ are presented as follows:

13
$$\frac{\partial \Phi_{\mathbf{R},2m-1}^{(L)}}{\partial x} = \begin{cases} \delta_{m,1} \left[\delta_{1,L} + \left(z - z_0 \right) \delta_{3,L} \right] & \left(x = x_{\mathrm{L},m}, -d_m < z < 0 \right) \\ \frac{\partial \Phi_{\mathbf{R},2m}^{(L)}}{\partial x} & \left(x = x_{\mathrm{L},m}, -h < z < -d_m \right) \end{cases}, \quad (16)$$

14
$$\frac{\partial \Phi_{\mathbf{R},2m+1}^{(L)}}{\partial x} = \begin{cases} \delta_{m,1} \left[\delta_{1,L} + \left(z - z_0 \right) \delta_{3,L} \right] & \left(x = x_{\mathbf{R},m}, -d_m < z < 0 \right) \\ \frac{\partial \Phi_{\mathbf{R},2m}^{(L)}}{\partial x} & \left(x = x_{\mathbf{R},m}, -h < z < -d_m \right) \end{cases}, \quad (17)$$

15
$$\Phi_{\mathrm{R},2m-1}^{(L)} = \Phi_{\mathrm{R},2m}^{(L)} \qquad \left(x = x_{\mathrm{L},m}, -h < z < -d_m\right),$$
 (18)

16
$$\Phi_{\mathrm{R},2m}^{(L)} = \Phi_{\mathrm{R},2m+1}^{(L)} \qquad \left(x = x_{\mathrm{R},m}, -h < z < -d_m\right),$$
 (19)

17 where $x_{L,m}$ and $x_{R,m}$ represent the horizontal positions of the left and right edges of subdomain 18 Ω_{2m} , respectively. 1 Upon substituting Eqs (3–6) for $\Phi_{\rm D}$ in different subdomains into the continuity conditions for

- 2 wave diffraction and Eqs.(11-14) for $\Phi_{\rm R}^{(L)}$ in different subdomains into Eqs.(16-19), utilizing the
- 3 orthogonality relations of the integration of eigen-functions over the vertical dimension (Zheng
- 4 and Zhang, 2016) and taking the first *M* terms in the infinite series, a linear system of 12*M*
- 5 complex equations for either $\Phi_{\rm D}$ or $\Phi_{\rm R}^{(L)}$ with the same number of unknown coefficients are
- 6 obtained. The unknown coefficients can be easily evaluated by solving a 12*M*-order linear matrix
- 7 equation.

8 2.4. Hydrodynamic coefficients due to wave diffraction/radiation

- 9 2.4.1 Direct Method (DM) for solving hydrodynamic coefficients
- 10 wave diffraction
- ¹¹ For fixed structures, the hydrodynamic forces acting on them called wave excitation forces are
- ¹² induced by both the undisturbed incident wave and the diffracted wave. The wave excitation

13 force loading on the float in mode L (L=1, 2, 3) can be written as $\operatorname{Re}\left(F_{e}^{(L)}e^{-i\omega t}\right)$, in which from

14 the view of the definition of "wave excitation force", $F_{e}^{(L)}$ is expressed as

15
$$F_{\rm e}^{(L)} = -i\omega\rho \int_{S_{\rm I}} (\Phi_{\rm I} + \Phi_{\rm D}) n_L \mathrm{d}s , \qquad (20)$$

where S_1 is the wetted surface of the float; n_L is the component in mode *L* of the generalized normal vector.

Similarly, the upward flux at the water surface inside the OWC chamber due to the contributionsof undisturbed incident wave and the diffracted wave, so-called the excitation volume flow, can

20 be written as

21
$$F_{\rm e}^{(4)} = \int_{x_{\rm R,2}}^{x_{\rm L,3}} \frac{\partial \left(\Phi_{\rm I} + \Phi_{\rm D}\right)}{\partial z} \Big|_{z=0} \,\mathrm{d}x \,. \tag{21}$$

- 22 wave radiation
- Radiation force acting on the float in mode i (i=1, 2, 3) can be treated as one that is induced by
- the oscillations of both the float and the OWC written as $\operatorname{Re}\left(F_{R}^{(i)}e^{-i\omega t}\right)$, in which

25

$$F_{R}^{(i)} = -i\omega\rho \int_{S_{l}} \left(\sum_{L=1}^{3} \dot{A}_{L} \Phi_{R}^{(L)} + p \Phi_{R}^{(4)} \right) n_{i} ds$$

$$= -i\omega\rho \int_{S_{l}} \sum_{L=1}^{4} \dot{A}_{L} \Phi_{R}^{(L)} n_{i} ds = \sum_{L=1}^{4} \dot{A}_{L} \left(i\omega a_{i,L} - c_{i,L} \right)$$
(22)

26 where $\dot{A}_4 = p$, $a_{i,L} = -\rho \int_{S_1} \operatorname{Re}(\Phi_{\mathbb{R}}^{(L)}) n_i ds$, and $c_{i,L} = -\rho \omega \int_{S_1} \operatorname{Im}(\Phi_{\mathbb{R}}^{(L)}) n_i ds$.

- 1 Similarly, the upward flux at the water surface inside the OWC chamber due to the radiated
- 2 waves induced by the oscillations of both the float and the OWC can be written as

$$F_{\rm R}^{(4)} = \int_{x_{\rm R,2}}^{x_{\rm L,3}} \frac{\partial \sum_{L=1}^{4} \dot{A}_{L} \varPhi_{\rm R}^{(L)}}{\partial z} \Big|_{z=0} dx$$

$$= \frac{\omega^{2}}{g} \sum_{L=1}^{4} \dot{A}_{L} \sum_{j=1}^{\infty} \int_{x_{\rm R,2}}^{x_{\rm L,3}} \left(A_{5,j}^{(L)} e^{\lambda_{j} x} + B_{5,j}^{(L)} e^{-\lambda_{j} x} \right) Z_{j}(0) dx$$

$$= \frac{\omega^{2}}{g} \sum_{L=1}^{4} \dot{A}_{L} \sum_{j=1}^{\infty} \frac{\left[A_{5,j}^{(L)} \left(e^{\lambda_{j} x_{\rm L,3}} - e^{\lambda_{j} x_{\rm R,2}} \right) - B_{5,j}^{(L)} \left(e^{-\lambda_{j} x_{\rm L,3}} - e^{-\lambda_{j} x_{\rm R,2}} \right) \right] Z_{j}(0)}{\lambda_{j}},$$

$$= \sum_{L=1}^{4} \dot{A}_{L} \left(i \omega a_{4,L} - c_{4,L} \right)$$

$$(23)$$

5
$$a_{4,L} = \frac{\omega}{g} \operatorname{Im}\left(\sum_{j=1}^{\infty} \frac{\left[A_{5,j}^{(L)} \left(e^{\lambda_{j} x_{L,3}} - e^{\lambda_{j} x_{R,2}}\right) - B_{5,j}^{(L)} \left(e^{-\lambda_{j} x_{L,3}} - e^{-\lambda_{j} x_{R,2}}\right)\right] Z_{j}(0)}{\lambda_{j}}\right), \quad (24)$$

$$6 \qquad c_{4,L} = -\frac{\omega^2}{g} \operatorname{Re}\left(\sum_{j=1}^{\infty} \frac{\left[A_{5,j}^{(L)} \left(e^{\lambda_j x_{L,3}} - e^{\lambda_j x_{R,2}}\right) - B_{5,j}^{(L)} \left(e^{-\lambda_j x_{L,3}} - e^{-\lambda_j x_{R,2}}\right)\right] Z_j(0)}{\lambda_j}\right).$$
(25)

7 Therefore,
$$F_{\rm R}^{(i)} = \sum_{L=1}^{4} \dot{A}_L \left(i \,\omega a_{i,L} - c_{i,L} \right)$$
 is valid for *i*=1, 2, 3, 4.

8 2.4.2 Indirect method for solving hydrodynamic coefficients

9 wave diffraction

10 In fact, apart from using the direct method as mentioned in Section 2.4.1, the generalized

excitation forces may also be expressed in terms of the radiated wave's far-field coefficients

using the Haskind Relation (HR). The excitation force (or the excitation volume flow) acting on a

- 13 body (or an OWC) that experiences a plane wave propagating from a certain direction is related
- to the body's (or the OWC's) ability to radiate a wave into just that direction (Falnes, 2002). The
 generalized wave excitation force after using the HR can be derived as:

16
$$F_{\rm e}^{(L)} = \frac{-2i\rho gAkhA_{\rm l,1}^{(L)} \left(-1\right)^{\delta_{4,L}}}{Z_{\rm l}(0)}, \qquad (26)$$

17 Detail derivation of Eq.(26) is given in Appendix A.

1 wave radiation

- 2 Similar to the expression of the generalized excitation forces using the Haskind Relation,
- 3 reciprocity relations exist for the radiation damping matrix (Falnes, 2002). By using the
- 4 reciprocity relations, some of the wave radiation damping and added mass can be written in terms

5 of the radiated wave's Far-Field Coefficients (FFC) as follows:

$$6 c_{i,L} = \omega \rho kh \left(A_{7,1}^{(i)*} A_{7,1}^{(L)} + A_{1,1}^{(i)*} A_{1,1}^{(L)} \right) (i = 1, 2, 3; L = 1, 2, 3), (i = L = 4), (27)$$

7
$$\mu_{i,L} = i\rho kh \Big(A_{7,1}^{(i)*} A_{7,1}^{(L)} + A_{1,1}^{(i)*} A_{1,1}^{(L)} \Big) \quad (i = 1, 2, 3; L = 4), (i = 4; L = 1, 2, 3), \quad (28)$$

8 where the superscript * denotes complex-conjugate.

9 2.5. Power absorption of the hybrid WEC

10 After solving the wave diffraction/radiation problem and obtaining the hydrodynamic

11 coefficients, the response of the hybrid WEC in frequency domain can be calculated using the

12 following dynamic motion equation:

$$\begin{bmatrix} -i\omega(\mathbf{M} + \mathbf{M}_{a} + \mathbf{M}_{PTO}) + (\mathbf{C}_{d} + \mathbf{C}_{PTO}) + i\mathbf{K}_{s}/\omega & \mathbf{A}_{J}^{T} \\ \mathbf{A}_{J} & \mathbf{0} \end{bmatrix} \begin{bmatrix} \dot{\mathbf{X}} \\ \mathbf{F}_{J} \end{bmatrix} = \begin{bmatrix} \mathbf{F}_{e} \\ \mathbf{0} \end{bmatrix}, \quad (29)$$

14 where **M** is the mass matrix; \mathbf{M}_a and \mathbf{C}_d are the added mass matrix and radiation damping matrix,

respectively; \mathbf{M}_{PTO} and \mathbf{C}_{PTO} are the mass matrix and damping matrix, respectively, induced by

16 the PTO system; \mathbf{K}_{s} is the hydrostatic restoring matrix; \mathbf{A}_{J} is the constraint matrix due to the

17 hinge restriction to the float; the superscript T denotes transpose; $\dot{X} = \begin{bmatrix} \dot{A}_1 & \dot{A}_2 & \dot{A}_3 & \dot{A}_4 \end{bmatrix}^T$

represents the velocity response vector of the hybrid WEC to be determined; F_J denotes the hinge force vector; F_e is the generalized wave excitation force vector.

20
$$\mathbf{A}_{J} = \begin{bmatrix} 1 & 0 & d & 0 \\ 0 & 1 & -D & 0 \end{bmatrix}, \ \mathbf{M} = \begin{bmatrix} m & & & \\ & m & & \\ & & I & \\ & & & 0 \end{bmatrix}, \ \mathbf{K}_{s} = \rho g \begin{bmatrix} 0 & & & & \\ & \frac{a_{1}^{3}}{12} - \frac{a_{1}d_{1}^{2}}{2} & & \\ & & \frac{a_{1}^{3}}{12} - \frac{a_{1}d_{1}^{2}}{2} & & \\ & & & 0 \end{bmatrix},$$
21
$$\mathbf{C}_{PTO} = \begin{bmatrix} 0 & & & & \\ & 0 & & & \\ & & c_{1} & & \\ & & & c_{2} \end{bmatrix}, \ \mathbf{M}_{PTO} = \begin{bmatrix} 0 & & & & \\ & 0 & & & \\ & & & \frac{V_{0}}{c_{a}^{2}\rho_{0}} \end{bmatrix},$$
(30)

in which *m* is the mass of the float; *I* is the rotary inertia of the float relative to the centre of mass;

23 c_1 and c_2 represent the linear damping of the hydraulic cylinder and the OWC turbine PTO

system, respectively; V_0 is the air chamber volume; c_a is the sound velocity in air; ρ_0 is the static

- 1 air density. In subsequent computations, $\rho/\rho_0=800$, $c_a=340$ m/s and the air chamber volume is
- 2 $V_0=2a^2$ unless otherwise specified.
- 3 Wave power is absorbed by the damping in both the float PTO system and the OWC PTO system.
- 4 After solving Eq.(29), \dot{X} is obtained and the average power that the hybrid WEC captures from
- 5 regular waves can be written as

6
$$P = \frac{1}{2} \left(c_1 \left| \dot{A}_3 \right|^2 + c_2 \left| \dot{A}_4 \right|^2 \right).$$
(31)

7 The power absorption efficiency is calculated as:

8
$$\eta = \frac{P}{0.5\rho g A^2 c_g},$$
(32)

9 where
$$c_g = \frac{\omega}{2k} \left[1 + \frac{2kh}{\sinh(2kh)} \right]$$
.

10 2.6. Optimization of power absorption

- 11 The power absorption capability of a WEC is a particular subject of interest. As described above,
- 12 although surge, heave and pitch modes of the float are all included in the float motion, only the
- 13 pitch motion, together with the oscillation of water column, are used to drive PTO systems.
- 14 Thanks to the mechanical relation between the surge, heave and pitch modes of the float induced
- by the hinge constraints, Eq. (29) can be reduced to the solution of a 2-order algebraic matrix
- 16 equation with the employment of matrix blocking method as follows.
- 17 Matrix $\left[-i\omega(\mathbf{M}+\mathbf{M}_{a}+\mathbf{M}_{PTO})+(\mathbf{C}_{d}+\mathbf{C}_{PTO})+i\mathbf{K}_{s}/\omega\right]$ can be partitioned into four blocks \mathbf{S}_{11} ,
- 18 S_{12} , S_{21} , and S_{22} whose sizes are all 2×2. The hinge force vector F_J can be expressed in terms of 19 wave excitation forces loading on the float in surge and heave modes, and the velocity response 20 of both the float in pitch mode and the air pressure inside the chamber as

21
$$\boldsymbol{F}_{\mathrm{J}} = \begin{cases} F_{\mathrm{e}}^{(1)} \\ F_{\mathrm{e}}^{(2)} \end{cases} - \begin{bmatrix} \mathbf{S}_{11} & \mathbf{S}_{12} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{\mathrm{T}} \\ \mathbf{I} \end{bmatrix} \begin{bmatrix} \dot{A}_{3} \\ \dot{A}_{4} \end{bmatrix} = \begin{cases} F_{\mathrm{e}}^{(1)} \\ F_{\mathrm{e}}^{(2)} \end{cases} - (\mathbf{S}_{11}\mathbf{A}_{\mathrm{T}} + \mathbf{S}_{12}) \begin{bmatrix} \dot{A}_{3} \\ \dot{A}_{4} \end{bmatrix}, \quad (33)$$

22 where
$$\mathbf{A}_{\mathrm{T}} = \begin{bmatrix} -d & 0 \\ D & 0 \end{bmatrix}$$
.

23 In addition, $F_{\rm J}$, $\dot{A}_{\rm a}$, $\dot{F}_{\rm e}^{(3)}$ and $F_{\rm e}^{(4)}$ should also satisfy the following relation:

24
$$\begin{bmatrix} \mathbf{S}_{21} & \mathbf{S}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{\mathrm{T}} \\ \mathbf{I} \end{bmatrix} \begin{bmatrix} \dot{A}_{3} \\ \dot{A}_{4} \end{bmatrix} - \mathbf{A}_{\mathrm{T}}^{\mathrm{T}} \mathbf{F}_{\mathrm{J}} = \begin{pmatrix} \mathbf{S}_{21} \mathbf{A}_{\mathrm{T}} + \mathbf{S}_{22} \end{pmatrix} \begin{bmatrix} \dot{A}_{3} \\ \dot{A}_{4} \end{bmatrix} - \mathbf{A}_{\mathrm{T}}^{\mathrm{T}} \mathbf{F}_{\mathrm{J}} = \begin{cases} F_{\mathrm{e}}^{(3)} \\ F_{\mathrm{e}}^{(4)} \end{cases} .$$
(34)

1 Submitting Eqs. (33-34) into Eq. (29) and making some rearrangements gives

$$2 \qquad \left(\mathbf{A}_{\mathrm{T}}^{\mathrm{T}}\mathbf{S}_{11}\mathbf{A}_{\mathrm{T}} + \mathbf{A}_{\mathrm{T}}^{\mathrm{T}}\mathbf{S}_{12} + \mathbf{S}_{21}\mathbf{A}_{\mathrm{T}} + \mathbf{S}_{22}\right) \begin{cases} \dot{A}_{3} \\ \dot{A}_{4} \end{cases} = \begin{cases} F_{\mathrm{e}}^{(3)} \\ F_{\mathrm{e}}^{(4)} \end{cases} + \mathbf{A}_{\mathrm{T}}^{\mathrm{T}} \begin{cases} F_{\mathrm{e}}^{(1)} \\ F_{\mathrm{e}}^{(2)} \end{cases}, \qquad (35)$$

in which the PTO damping coefficients (c_1 and c_2) can be easily separated, and Eq. (35) can be rewritten into a 2-order linear matrix equation:

5
$$\begin{bmatrix} A_0 + c_1 & B_0 \\ C_0 & D_0 + c_2 \end{bmatrix} \begin{bmatrix} \dot{A}_3 \\ \dot{A}_4 \end{bmatrix} = \begin{bmatrix} E_0 \\ F_0 \end{bmatrix}, \quad (36)$$

6 where the subscript "0" of $A_0 \sim F_0$ means that these parameters are independent of c_1 and c_2 .

7 After expressing \dot{A}_3 and \dot{A}_4 in terms of $A_0 \sim F_0$, c_1 and c_2 , and submitting them into Eq. (31), we 8 have the new expression of *P* as a two variable explicit function

9
$$P(c_1, c_2) = \frac{1}{2} \frac{c_1(u_1c_2^2 + u_2c_2 + u_3) + c_2(u_4c_1^2 + u_5c_1 + u_6)}{c_1^2c_2^2 + u_7c_1^2c_2 + u_8c_1c_2^2 + u_9c_1^2 + u_{10}c_2^2 + u_{11}c_1c_2 + u_{12}c_1 + u_{13}c_2 + u_{14}}, \quad (37)$$

10 where $u_1 \sim u_{14}$ are expressed in terms of $A_0 \sim F_0$: $u_1 = |E_0|^2$, $u_2 = 2 \operatorname{Re} \Big[E_0^* (D_0 E_0 - B_0 F_0) \Big]$,

11
$$u_3 = |D_0 E_0 - B_0 F_0|^2$$
, $u_4 = |F_0|^2$, $u_5 = 2 \operatorname{Re} \left[F_0^* (A_0 F_0 - C_0 E_0) \right]$, $u_6 = |A_0 F_0 - C_0 E_0|^2$, $u_7 = 2 \operatorname{Re} (D_0)$,
12 $2 \operatorname{Re} (A_0) = |D_0|^2$, $u_7 = 2 \operatorname{Re} (D_0)$

12
$$u_8 = 2\operatorname{Re}(A_0), \quad u_9 = |D_0|^2, \quad u_{10} = |A_0|^2, \quad u_{11} = 2\operatorname{Re}(A_0D_0 - B_0C_0 + A_0D_0^*),$$

13
$$u_{12} = 2 \operatorname{Re} \left[D_0^* \left(A_0 D_0 - B_0 C_0 \right) \right], \quad u_{13} = 2 \operatorname{Re} \left[A_0^* \left(A_0 D_0 - B_0 C_0 \right) \right], \quad u_{14} = \left| A_0 D_0 - B_0 C_0 \right|^2.$$

The frequency dependent maximum of absorbed power, denoted as
$$P_0(\omega)$$
, can be achieved
when $\partial P/\partial c_1 = 0$ and $\partial P/\partial c_2 = 0$. While for some rare cases, the maximum value of *P* may
occur at either c_1 or c_2 being 0 or $+\infty$.

17 For
$$c_2=0$$
, $P = \frac{1}{2} \frac{u_3 c_1}{u_9 c_1^2 + u_{12} c_1 + u_{14}}$ and the maximum absorbed power, denoted as P_1 , occurs if

18
$$c_1 = \sqrt{u_{14}/u_9}$$
, for which we have $P_1 = \frac{1}{2} \frac{u_3 \sqrt{u_{14}/u_9}}{2u_{14} + u_{12} \sqrt{u_{14}/u_9}}$;

19 For $c_1=0$, $P = \frac{1}{2} \frac{u_6 c_2}{u_{10} c_2^2 + u_{13} c_2 + u_{14}}$ and the maximum absorbed power, denoted as P_2 , occurs if

20
$$c_2 = \sqrt{u_{14}/u_{10}}$$
, for which we have $P_2 = \frac{1}{2} \frac{u_6 \sqrt{u_{14}/u_{10}}}{2u_{14} + u_{13} \sqrt{u_{14}/u_{10}}}$;

1 For $c_2 = +\infty$, $P = \frac{1}{2} \frac{u_1 c_1}{c_1^2 + u_8 c_1 + u_{10}}$ and the maximum absorbed power, denoted as P_3 , occurs if

2
$$c_1 = \sqrt{u_{10}}$$
, for which we have $P_3 = \frac{1}{2} \frac{u_1 \sqrt{u_{10}}}{2u_{10} + u_8 \sqrt{u_{10}}}$

3 For $c_1 = +\infty$, $P = \frac{1}{2} \frac{u_4 c_2}{c_2^2 + u_7 c_2 + u_9}$ and the maximum absorbed power, denoted as P_4 , occurs if

4 $c_2 = \sqrt{u_9}$, for which we have $P_4 = \frac{1}{2} \frac{u_4 \sqrt{u_9}}{2u_9 + u_7 \sqrt{u_9}}$.

6

5 In summary, the maximum absorbed power by the hybrid WEC, denoted as P_{max} is

$$P_{\max} = \max(P_0, P_1, P_2, P_3, P_4).$$
(38)

7 The maximum power absorption efficiency for P_{max} can be calculated in a similar way as given in 8 Eq. (32), which is notated by η_{max} . The corresponding optimized PTO damping for the float and 9 the OWC are notated by $c_{\text{opt},1}$ and $c_{\text{opt},2}$, respectively.

10 2.7. Wave reflection and transmission coefficients

11 The spatial velocity potential in the distance far away from the hybrid WEC can be written as:

12
$$\Phi(-x_{\infty},0) = -\frac{\mathrm{i}g}{\omega} \frac{Z_{1}(z)}{Z_{1}(0)} \left[A \mathrm{e}^{-\mathrm{i}kx_{\infty}} + \frac{\mathrm{i}\omega}{g} Z_{1}(0) \left(A_{1,1}^{\mathrm{D}} + \sum_{L=1}^{4} \dot{A}^{(L)} A_{1,1}^{\mathrm{R},L} \right) \mathrm{e}^{\mathrm{i}kx_{\infty}} \right], \quad (39)$$

13
$$\Phi(x_{\infty}, 0) = -\frac{\mathrm{i}g}{\omega} \frac{Z_1(z)}{Z_1(0)} \left[A \mathrm{e}^{\mathrm{i}kx_{\infty}} + \frac{\mathrm{i}\omega}{g} Z_1(0) \left(A_{7,1}^{\mathrm{D}} + \sum_{L=1}^{4} \dot{A}^{(L)} A_{7,1}^{\mathrm{R},L} \right) \mathrm{e}^{\mathrm{i}kx_{\infty}} \right].$$
(40)

14 Therefore, the wave reflection coefficient and the wave transmission coefficient of the WEC,

15 denoted as *R* and *T*, respectively, can be calculated as:

16
$$R = \left| \frac{\omega}{gA} Z_0(0) \left(A_{1,1}^{\rm D} + \sum_{L=1}^4 \dot{A}^{(L)} A_{1,1}^{\rm R,L} \right) \right|, \tag{41}$$

17
$$T = \left| 1 + \frac{\mathrm{i}\omega}{gA} Z_0(0) \left(A_{7,1}^{\mathrm{D}} + \sum_{L=1}^{4} \dot{A}^{(L)} A_{7,1}^{\mathrm{R},L} \right) \right|.$$
(42)

18 **3. Model validation**

To validate the solutions of wave diffraction and radiation problems in the analytical model as
described in Section 2, wave excitation forces/volume flux, added mass and radiation damping
are all evaluated by using both direct method and indirect method. By checking these results of

- 1 the certain hydrodynamic parameters using different methods, the solutions of wave diffraction
- 2 and radiation problems can be validated if good agreements are satisfied. What is more,
- 3 hydrodynamic performance of an OWC consisting of two vertical thin barriers with unequal
- 4 length is also evaluated and is compared with published results (Falnes and McIver, 1985). The
- 5 theoretical maximum power absorption of the hybrid WEC, wave reflection and transmission
- 6 coefficients can be validated by comparing with the results from trial-and-error method and by
- 7 checking the energy conservation identity, respectively.
- 8 The excitation forces/volume flux and hydrodynamic coefficients together with both float PTO
- 9 damping and OWC PTO damping are normalized as follows:

$$\mathbf{I0} \qquad \overline{F}_{e}^{(j)} = \begin{cases} \frac{|F_{e}^{(j)}|}{\rho g A h^{2}}, \ j = 1, 2 \\ \frac{|F_{e}^{(j)}|}{\rho g A h^{2}}, \ j = 3 \end{cases}, \ \overline{c}_{i,j} = \begin{cases} \frac{c_{i,j}}{\rho h^{2} \sqrt{g h}}, \ (i = 1, 2; j = 3), (i = 3; j = 1, 2) \\ \frac{c_{i,j}}{\rho h^{2} \sqrt{g h}}, \ (i = 1, 2; j = 4), (i = 4; j = 1, 2) \end{cases}, \\ \frac{c_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 3 \\ \frac{c_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 4 \end{cases}$$

$$\mathbf{I1} \qquad \overline{\mu}_{i,j} = \begin{cases} \frac{\partial \mu_{i,j}}{\rho h^{2} \sqrt{g h}}, \ (i = 1, 2; j = 4), (i = 4; j = 3) \\ \frac{\partial \mu_{i,j}}{\rho h^{2} \sqrt{g h}}, \ (i = 1, 2; j = 3), (i = 3; j = 1, 2) \\ \frac{\partial \mu_{i,j}}{\rho h^{2} \sqrt{g h}}, \ (i = 1, 2; j = 3), (i = 3; j = 1, 2) \\ \frac{\partial \mu_{i,j}}{\rho h^{3} \sqrt{g h}}, \ (i = 1, 2; j = 4), (i = 4; j = 1, 2) \end{cases}, \\ \frac{\partial \mu_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 3 \\ \frac{\partial \mu_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 3 \\ \frac{\partial \mu_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 3 \\ \frac{\partial \mu_{i,j}}{\rho h^{3} \sqrt{g h}}, \ i = j = 4 \end{cases}$$

12
$$\overline{\dot{x}} = \frac{\dot{x}\sqrt{gh}}{Ag}, \quad \overline{p} = \frac{p}{\rho gA}, \quad \overline{c}_{opt}^{(1)} = \frac{c_{opt,1}}{\rho h^3 \sqrt{gh}}, \quad \overline{c}_{opt}^{(2)} = \frac{\rho g c_{opt,2}}{\sqrt{gh}}.$$

- 13 Figure 3 gives the results of wave excitation forces/volume flux for the hybrid WEC with
- 14 $a_1/h=0.1, a_2/h=a_3/h=0.005, d_1/h=0.025, d_2/h=0.1, d_3/h=0.15, D/h=0.15, a/h=0.1$. The
- 15 corresponding wave damping and added mass are illustrated in Figs. 4 and 5, respectively.

4 Fig. 3 Wave excitation forces/volume flux for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$, $d_2/h=0.1$,

 $d_3/h=0.15$, D/h=0.15, a/h=0.1: (a) Dimensionless magnitudes of surge and heave wave excitation 5

forces acting on the float; (b) Phases of surge and heave wave excitation forces acting on the 6

7 float; (c) Dimensionless magnitudes of pitch wave excitation force acting on the float and wave

8 excitation volume flux of the OWC; (d) Phases of pitch wave excitation force acting on the float

9 and wave excitation volume flux of the OWC.

Fig. 4 Wave radiation damping for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$, $d_2/h=0.1$, $d_3/h=0.15$, D/h=0.15, a/h=0.1: (a) Wave radiation damping of the float in surge mode due to the oscillation of the float in surge and heave modes; (b) Wave radiation damping of the float in surge and heave modes due to the oscillation of the float in pitch mode; (c) Wave radiation damping of the float in heave and pitch modes due to the oscillation of the float in heave and pitch modes, respectively; (d) Wave radiation damping of the OWC due to the air pressure oscillation inside the OWC chamber.

- 1 Fig. 5 Added mass for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$, $d_2/h=0.1$, $d_3/h=0.15$, D/h=0.15,
- 2 a/h=0.1: (a) Added mass of the float in surge and heave modes due to the air pressure oscillation
- 3 inside the OWC chamber; (b) Added mass of the float in pitch mode due to the air pressure
- 4 oscillation inside the OWC chamber.
- 5 As shown in Figs. 3~5, results of the wave excitation forces/volume flux, wave damping and
- 6 added mass of the hybrid WEC by using direct and indirect methods agree perfectly with each
- 7 other.
- 8 Previously, Falnes and McIver (1985) used to study the power absorption by an OWC, which is
- 9 composed of two vertical thin barriers with unequal length. Here, after setting the float width,
- 10 float submergence depth and thickness of both fore wall and aft wall of OWC chamber to rather
- small values, the hybrid WEC looks rather similar with the device studied by Falnes and McIver
- 12 (1985). The obtained results of wave excitation volume flux and the corresponding hydrodynamic
- 13 coefficients for $a_1/h = a_2/h = a_3/h = 0.001$, $d_1/h = 0.001$, $d_2/h = 0.15$, $d_3/h = 0.25$, D/h = 0.001, a/h = 0.1 are
- compared with those from Falnes and McIver (1985) in Figs. 6 and 7.

16 Fig. 6 Dimensionaless excitation volume flux versus *ka* for the chosen geometrical parameters:

- 17 $d_2/h=0.15, d_3/h=0.25, a/h=0.1.$ (a) Amplitude; (b) Phase. (Normalizing principle adopted by
- 18 Falnes and McIver (1985) is applied to the present figure)

19

Fig. 7 Dimensionaless radiation damping and added mass versus *ka* for the chosen geometrical parameters: $d_2/h=0.15$, $d_3/h=0.25$, a/h=0.1. (a) Radiation damping coefficient; (b) Added mass

coefficient. (Normalizing principle adopted by Falnes and McIver (1985) is applied to the present
figure)

6 The good agreement between the obtained results and those from Falnes and McIver (1985) is

7 also obtained as plotted in Figs. 6 and 7. It can be learnt from Figs. 3~7 that the present analytical

8 model performs quite well in solving wave diffraction and radiation problems of the hybrid WEC.

- 9 Figure 8a illustrates the comparison between the analytical results of the maximum power
- 10 absorption efficiency and the numerical ones using trial-and-error method for $a_1/h=0.1$, $a_2/h=$
- 11 $a_3/h=0.005, d_1/h=0.025, d_2/h=0.1, d_3/h=0.15, D/h=0.15, a/h=0.1, d/h=0.05$. The trial-and-error
- 12 method is adopted for searching the maximum efficiency in the frame of $\overline{c}^{(1)} \in [0, 0.025]$ and

13 $\overline{c}^{(2)} \in [0, 8.0]$. The corresponding optimized float PTO damping and OWC PTO damping are

14 also given in Fig.8b. Analytical and numerical results of η_{max} , $\overline{c}_{\text{opt}}^{(1)}$ and $\overline{c}_{\text{opt}}^{(2)}$ are found to be in

15 very good agreement for different wave conditions.

- 1 Fig.8 Variation of η_{max} , $\overline{c}_{\text{opt}}^{(1)}$ and $\overline{c}_{\text{opt}}^{(2)}$ with *kh* for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$,
- 2 $d_2/h=0.1, d_3/h=0.15, D/h=0.15, a/h=0.1, d/h=0.05$: (a) η_{max} ; (b) $\overline{c}_{\text{opt}}^{(1)}$ and $\overline{c}_{\text{opt}}^{(2)}$.
- 3 Figure 9 shows the results of η , R, T and $\eta + R^2 + T^2$ varying with kh for $a_1/h=0.1$, $a_2/h=$
- 4 $a_3/h=0.005, d_1/h=0.025, d_2/h=0.1, d_3/h=0.15, D/h=0.15, a/h=0.1, d/h=0.05, \overline{c}^{(1)}=0.001$ and $\overline{c}^{(2)}$
- 5 =0.5. The energy conservation relationship $\eta + R^2 + T^2 = 1$ is satisfied perfectly, which indirectly
- 6 validates the present analytical model as well.

8 Fig.9 Variation of η , R, T and $\eta + R^2 + T^2$ with kh for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$,

9 $d_2/h=0.1, d_3/h=0.15, D/h=0.15, a/h=0.1, d/h=0.05, \overline{c}^{(1)}=0.001$ and $\overline{c}^{(2)}=0.5$.

10 Although the hybrid WEC can be used as a kind of floating breakwaters by reducing amplitude of

11 the wave transmitted far behind the device, in the following sections, the study is mainly focused

12 on the performance in wave power exploitation.

13 **4. Model Application**

14 4.1. Comparison between the hybrid WEC and the isolated float and OWC

15 To study the influence of the hydrodynamic interaction between the float and the OWC on power

absorption of the hybrid WEC, the wave power absorbed by the isolated float and OWC working

- in open sea, as show in Fig. 10, are also evaluated, respectively, as a comparison with that of the
- 18 hybrid WEC.

Fig. 10 Sketches of the isolated OWC and the isolated hinged float: (a) isolated float; (b) isolated
 OWC

4 The wave excitation forces and hydrodynamic coefficients of an isolated float (as shown in Fig.10a) can be evaluated using the analytical model proposed by Zheng et al. (2014). Analytical 5 6 solution of wave diffraction and radiation by the isolated OWC (as shown in Fig.10b) can be 7 derived base on the study carried out by Zheng and Zhang (2016). As both the oscillating motion 8 of the isolated float and that of the isolated OWC can be treated as an oscillating system with only 9 one degree of freedom, the maximized absorbed power and the corresponding optimal PTO damping for each situation can be calculated quite easily by solving a partial differential equation 10 of single degree of freedom (Falnes, 2002). 11

12 Figure 11 illustrates the frequency response comparison of the maximum power capture 13 efficiency of the hybrid WEC and those of the hinged float and the OWC when they are 14 independently deployed for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$, $d_2/h=0.1$, $d_3/h=0.15$, D/h=0.15, a/h=0.1, d/h=0.05. For kh<10, the maximum power capture efficiency of the hinged 15 float, $\eta_{\text{max}}^{(1)}$, is no more than 0.3. While as *kh* increases from 0 to 10, the maximum efficiency of 16 the isolated OWC, $\eta_{\text{max}}^{(2)}$, first increases and then decreases after reaching the peak value of 0.87 at 17 *kh*=6.0 with a narrow bandwidth. $\eta_{\text{max}}^{(2)}$ >0.8 only occurs at 5.7<*kh*<6.4. After combining these 18 19 segments together, i.e., the hybrid WEC, the power extraction capacity is significantly improved. 20 For 7.1<*kh*<8.0, almost all the incident power can be captured when the PTO damping 21 coefficients are optimized. What is better, the frequency bandwidth for $\eta_{max} > 0.8$ is 4.6<kh<8.7, 22 much wider than that of the isolated OWC. It is very interesting to find that if the hinged float in the absence of the OWC and the OWC in the absence of the hinged float are considered, 23 respectively, the efficiency of both of them $(\eta_{\max}^{(1)} + \eta_{\max}^{(2)})$ is smaller than the efficiency of the 24 hybrid WEC (η_{max}) for 1.4<*kh*<5.1 and 6.7<*kh*<9.0, as shown in Fig.11. And the frequency 25 bandwidth of η_{\max} of the hybrid WEC is larger than those of both the isolated hinged float and 26 isolated OWC ($\eta_{\text{max}}^{(1)} + \eta_{\text{max}}^{(2)}$) for $\eta > 50\%$. This means that the hydrodynamic interaction between 27 28 the float and the OWC plays a positive effect on both the power absorption for some range of

- 1 wave conditions and frequency response width of the hybrid WEC. Although the peak value of
- 2 $\eta_{\rm max}$ of the hybrid WEC is smaller than that of both the isolated hinged float and isolated OWC,
- 3 it is believed that the hybrid WEC can be used to a wider range of wave conditions with a rather
- 4 high power absorption efficiency. In the random waves with more incident power distributed at
- 5 1.4 < kh < 5.1 and 6.7 < kh < 9.0, output power of the hybrid WEC could be larger than the sum of
- 6 output power of both the isolated hinged float and isolated OWC.

8 Fig. 11 Variation of η_{max} , $\eta_{\text{max}}^{(1)}$ and $\eta_{\text{max}}^{(2)}$ with *kh* for $a_1/h=0.1$, $a_2/h=a_3/h=0.005$, $d_1/h=0.025$, 9 $d_2/h=0.1$, $d_3/h=0.15$, D/h=0.15, a/h=0.1, d/h=0.05.

10 4.2. Impact analysis on power absorption by multiple parameters

11 4.2.1 Effect of OWC chamber width

12 Figure 12 shows the frequency response of η_{max} for various OWC chamber widths (*a/h*). Due to

13 the existence of the hinged float, the η_{max} -kh curve of the hybrid WEC could hold more peaks

14 with some specified structural dimensions (as given in Fig. 12), rather than merely one single

15 peak for an isolated stationary offshore OWC (Elhanafi et al., 2017). For kh < 5.0, the larger a/h is,

16 the larger η_{max} by the hybrid WEC can be achieved whereas when 6.0<*kh*<6.5 *a/h* shows the

- 17 opposite effect on η_{max} . It is noted that once a/h is doubled from 0.05 to 0.10, the maximum
- 18 increase in η_{max} can reach 40%. However, the influence of a/h on η_{max} is not obvious for long
- 19 wave length and short wave length, such as kh < 2.5 and kh > 7.5. As OWC chamber width (a/h)
- 20 increases from 0.05 to 0.15, the value of kh, where the second peak of η_{max} -kh curve occurs,
- 21 decreases from 6.7 to 5.3.

3

Fig. 12 Variation of η_{max} for various OWC chamber width (*a/h*) with *a*₁/*h*=0.05, *a*₂/*h*= *a*₃/*h*=0.005, *d*₁/*h*=0.05, *d*₂/*h*=0.1, *d*₃/*h*=0.15, *D*/*h*=0.1, *d*/*h*=0.1.

4 4.2.2 Effect of submergence of the OWC side walls

5 The frequency response of η_{max} for various submergences of the OWC fore wall (d_2/h) is plotted

6 in Fig. 13. It shows that, for kh < 4.0, a larger value of d_2/h is welcome for capturing power from

7 waves. This result is consistent with the corresponding numerical one for an offshore stationary

8 OWC, that the energy extraction in long waves can be improved with the increase of the

9 submergence of lips (Elhanafi et al., 2017). Compared to the other device with a larger d_2/h , the

10 hybrid WEC with the smallest d_2/h (=0.05) has the least power capture capacity for all the wave

11 conditions studied (kh < 10). However, increasing d_2/h will not play a positive effect on power

12 absorption for all kh. For example, when kh=5.8, the corresponding η_{max} is 0.8 for $d_2/h=0.10$,

13 which is obviously larger than those for $d_2/h=0.05$, 0.15, and 0.20.

14

Fig. 13 Variation of η_{max} for various submergence of the OWC side walls (d_2/h) with $a_1/h=0.05$, $a_2/h=a_3/h=0.005$, $d_1/h=0.05$, $d_3/h=d_2/h+0.05$, a/h=0.1, D/h=0.1, d/h=0.1.

- 1 4.2.3 Effect of float width
- 2 As another vital parameter affecting power absorption of the hybrid WEC, influence of float
- 3 width (a_1/h) is illustrated in Fig. 14. It can be learned that the first and second peaks of the η_{max} -
- 4 *kh* curve, occurring at 1.0<*kh*<4.0 and 4.4<*kh*<7.2, respectively, both are quite sensitive to a_1/h .
- 5 The larger a_1/h is, the larger the first peak value of η_{max} and the corresponding kh are, whereas
- 6 the larger a_1/h is, the smaller the second peak value of η_{max} and the corresponding kh are. While
- 7 for 4.4<*kh*<7.2, more power can be absorbed by the hybrid WEC with a smaller a_1/h . Thus,
- 8 within $kh \in [1.0, 7.2]$ in which the water depth is specifically given, for waves with a smaller
- 9 wave length (or high wave frequency) there is a demand to deploy a hybrid WEC device with a
- smaller a_1/h to realize more power absorption whereas for waves with a larger wave length there
- 11 is a demand to deploy a hybrid WEC device generally with a larger a_1/h , which is mainly due to
- 12 its larger peak value of power absorption efficiency and wider response width.

14 Fig. 14 Variation of η_{max} for various float width (a_1/h) with $a_2/h = a_3/h = 0.005$, $d_1/h = 0.05$, 15 $d_2/h = 0.1$, $d_3/h = 0.15$, a/h = 0.1, D/h = 0.1, d/h = 0.1.

16 4.3.4 Effect of float draft

Figure 15 shows the variation of η_{max} with kh for various float draft (d_1/h) ranging from 0.025 to 17 0.1. For $d_1/h=0.025$, as kh increases from 0 to 10, η_{max} first increases and then tends to be stable 18 after reaching 0.95 at kh=5.4. As a comparison, the η_{max} -kh curves representing the rest cases 19 20 with a larger d_1/h are quite different from that for $d_1/h=0.025$. A sharp peak happens at 0 < kh < 3.021 for $d_1/h=0.050$, 0.075, and 0.100, respectively. The hybrid WEC with a larger d_1/h means a 22 smaller first resonant frequency of the float, therefore the sharp peak moves toward the left side 23 of the kh axis. It can be seen that for waves with long wave length, there is a need of a larger d_1/h to match waves so as to acquire a larger η_{\max} , but this is at the expense of narrowing the 24 25 frequency response width. Therefore, for waves with long wave length and a certain frequency 26 width, even though the natural frequency of the device matches the waves to obtain the peak 27 value of η_{\max} , the total power absorbed by the WEC is still quite limited due to a narrower 28 frequency response bandwidth. It can be seen clearly that, for waves with short wave length (or

- 1 high wave frequency) and a certain frequency width, wave energy is converted efficiently, and
- 2 the smaller the float draft (d_1/h) is, generally the larger the total power absorbed is.

4 Fig. 15 Variation of η_{max} for various float draft (d_1/h) with $a_1/h=0.05$, $a_2/h=a_3/h=0.005$, 5 $d_2/h=0.1$, $d_3/h=0.15$, a/h=0.1, D/h=0.1, d/h=0.1.

6 4.3.5 Effect of the distance between float center and OWC

7 The distance between float center and OWC (D/h) plays an important role in affecting the

8 hydrodynamic interaction between the float and the OWC. Effect of D/h on the maximum power

9 absorption efficiency can be found in Fig. 16. As D/h increases from 0.075 to 0.2 with the step of

10 0.025, the first peak value of η_{max} -kh curve increases proportionally from 0.48 to 0.88, and its

11 corresponding *kh* also increases from 1.5 to 5.3. Therefore, for a smaller wave frequency there is

12 a demand to deploy a hybrid WEC with a smaller D/h in order to achieve the maximum power

13 absorption efficiency. Conversely, a hybrid WEC with a larger D/h need be deployed. It has to be

14 noted that the smaller D/h is, the smaller the frequency response bandwidth of the hybrid WEC is.

15

3

16 Fig. 16 Variation of η_{max} for various distance between float center and OWC (*D/h*=0.1) with 17 $a_1/h=0.05, a_2/h=a_3/h=0.005, d_1/h=0.05, d_2/h=0.1, d_3/h=0.15, a/h=0.1, d/h=0.1.$

- 1 4.3.6 Effect of vertical hinge position of the rigid arm
- 2 Although the vertical hinge position of the rigid arm (d/h) does not affect the basic hydrodynamic
- 3 coefficients of the hybrid WEC as calculated in the analytical model, it has a significant influence
- 4 on the rotary stiffness and inertia of the hinged float. Hence the motion response and power
- 5 absorption can also be changed by varying d/h, as shown in Fig. 17. As d/h increases from 0.005
- 6 to 0.125, the rotary inertia of the float relative to the hinge position increases as well, resulting in
- 7 a smaller resonant frequency together with a smaller first peak value of η_{max} .

9 Fig. 17 Variation of η_{max} for various vertical hinge position of the rigid arm (*d/h*) with 10 $a_1/h=0.05, a_2/h=a_3/h=0.005, d_1/h=0.05, d_2/h=0.1, d_3/h=0.15, a/h=0.1, D/h=0.1.$

11 **5. Conclusions**

We propose a hybrid WEC device consisting of a fixed inverted flume with long length and a bottom hole, and a long floating cube hinged with the flume. An analytical model is developed for the power extraction of the device based on linear potential flow theory and eigen-function

15 matching method in the two-dimensional Cartesian coordinate system.

The wave excitation forces/volume flux, added mass and wave damping are all calculated by the 16 17 analytical model using different approaches. Additionally, hydrodynamic performance of an 18 OWC consisting of two vertical thin barriers with unequal length is also evaluated and is 19 compared with published results (Falnes and McIver, 1985). The good agreement of these results 20 between each other shows that the present analytical model is correct. In addition, the analytical 21 results of the maximum power absorbed by the device is compared with those using trial-and-22 error method. Energy conservation relationship is also checked to indirectly validate the present 23 analytical model. 24 The validated analytical model is then adopted to carry out the study on power capture capability

of the device with different geometrical dimension. For some specified dimensions, results are

also compared with a parallel study of an isolated OWC and an isolated float. Results reveal that:

- 27 the power extraction capacity can be significantly improved for a wide range of wave conditions
- after combining the isolated OWC and the isolated float together. The hydrodynamic interaction

- 1 between the float and the OWC plays a positive effect on power absorption of the hybrid WEC
- 2 for some certain wave conditions.
- 3 It is found that the influence of device geometry on the power absorption can be significant and
- 4 varies considerably, depending on wave length. For 3.0<*kh*<4.0, the hybrid WEC with a larger
- 5 water column width inside the OWC chamber, a larger submergence of the side walls of the
- 6 OWC chamber, a larger float width, while a smaller float draft is welcome in absorbing more
- 7 power from incident waves. As *kh* increase from 0 towards 5.0, there is generally a peak value of
- 8 η_{max} -*kh* curve, which turns larger for the hybrid WEC with a larger water column width inside

9 the OWC chamber, a larger submergence of the side walls of the OWC chamber, a larger float

- 10 width, a larger distance between the float center and the fore wall of OWC, a smaller float draft
- 11 and a smaller height of the hinge relative to the mean water surface.

12 The analytical model proposed in this paper can be applied to study the wave attenuation by the

13 floating breakwaters consisting of a float and an OWC. The wave power absorption obtained by

14 using the potential flow theory in this paper may be overestimated without consideration of water

viscous effect. Such viscous effect on the hybrid WEC device might be investigated by using

16 physical experiments in the future. The present work concentrates on analysis of the performance

17 of a two-dimensional hybrid WEC. Analytical study on the power extraction of a three-

18 dimensional hybrid WEC will be reported elsewhere.

Appendix A. Expression of the generalized excitation forces in terms of the radiated wave's far-field coefficients

Since $\Phi_{R}^{(L)}$ (*L*=1, 2, 3) is the spatial velocity potential due to unit amplitude velocity oscillation of the float in mode *L*, the component in mode *L* of the generalized normal vector n_L can be written as

28
$$n_L = \frac{\partial \Phi_{\rm R}^{(L)}}{\partial n}, \qquad (A1)$$

29 therefore, Eq. (20) can be rewritten as

30
$$F_{\rm e}^{(L)} = -i\omega\rho \int_{S_{\rm I}} \left(\Phi_{\rm I} + \Phi_{\rm D} \right) \frac{\partial \Phi_{\rm R}^{(L)}}{\partial n} \, \mathrm{d}s = -i\omega\rho \int_{S_{\rm I}} \left(\Phi_{\rm I} \frac{\partial \Phi_{\rm R}^{(L)}}{\partial n} + \Phi_{\rm D} \frac{\partial \Phi_{\rm R}^{(L)}}{\partial n} \right) \, \mathrm{d}s \,. \tag{A2}$$

31 According to Green's theorem (Falnes, 2002), we have

1
$$\int_{S_{\rm I}} \left(\boldsymbol{\Phi}_{\rm D} \frac{\partial \boldsymbol{\Phi}_{\rm R}^{(L)}}{\partial n} - \boldsymbol{\Phi}_{\rm R}^{(L)} \frac{\partial \boldsymbol{\Phi}_{\rm D}}{\partial n} \right) \mathrm{d}s = -\int_{S_{\pm\infty}} \left(\boldsymbol{\Phi}_{\rm D} \frac{\partial \boldsymbol{\Phi}_{\rm R}^{(L)}}{\partial n} - \boldsymbol{\Phi}_{\rm R}^{(L)} \frac{\partial \boldsymbol{\Phi}_{\rm D}}{\partial n} \right) \mathrm{d}s = 0, \quad (A3)$$

- 2 where $S_{\pm\infty}$ represents the boundaries at infinite, i.e., $x=\pm\infty$.
- 3 Hence, together with employment of the boundary condition of wave diffraction at wetted

4 surface, i.e., $\partial \Phi_{\rm D} / \partial n = -\partial \Phi_{\rm I} / \partial n$, we have

5
$$F_{e}^{(L)} = -i\omega\rho \int_{S_{I}} \left(\Phi_{I} \frac{\partial \Phi_{R}^{(L)}}{\partial n} + \Phi_{R}^{(L)} \frac{\partial \Phi_{D}}{\partial n} \right) ds = -i\omega\rho \int_{S_{I}} \left(\Phi_{I} \frac{\partial \Phi_{R}^{(L)}}{\partial n} - \Phi_{R}^{(L)} \frac{\partial \Phi_{I}}{\partial n} \right) ds , (A4)$$

- 6 which is one way of formulating the so-called Haskind relation.
- 7 If we reuse Green's theorem, wave excitation forces can be written as

8
$$F_{\rm e}^{(L)} = i\omega\rho \int_{S_{\pm\infty}} \left(\Phi_{\rm I} \frac{\partial \Phi_{\rm R}^{(L)}}{\partial n} - \Phi_{\rm R}^{(L)} \frac{\partial \Phi_{\rm I}}{\partial n} \right) {\rm d}s \,. \tag{A5}$$

9 The incident wave potential is generally given as:

10
$$\Phi_{\rm I} = -\frac{{\rm i}gA{\rm e}^{ikx}}{\omega} \frac{\cosh\left[k\left(z+h\right)\right]}{\cosh\left(kh\right)} = -\frac{{\rm i}gA{\rm e}^{ikx}}{\omega} \frac{Z_{\rm I}(z)}{Z_{\rm I}(0)}.$$
 (A6)

11 After inserting Eqs. (11),(14) and (A6) into Eq.(A5),

12

$$F_{e}^{(L)} = i\omega\rho \left[\int_{S_{+\infty}} \left(\varphi_{I} \frac{\partial \varphi_{R}^{(L)}}{\partial n} - \varphi_{R}^{(L)} \frac{\partial \varphi_{I}}{\partial n} \right) ds + \int_{S_{-\infty}} \left(\varphi_{I} \frac{\partial \varphi_{R}^{(L)}}{\partial n} - \varphi_{R}^{(L)} \frac{\partial \varphi_{I}}{\partial n} \right) ds \right]$$

$$= i\omega\rho \left[\int_{S_{+\infty}} \left(ik\varphi_{I}\varphi_{R}^{(L)} - ik\varphi_{R}^{(L)}\varphi_{I} \right) ds + \int_{S_{-\infty}} \left(-ik\varphi_{I}\varphi_{R}^{(L)} - ik\varphi_{R}^{(L)}\varphi_{I} \right) ds \right]$$

$$= i\omega\rho \left(-2ik \right) \int_{-h}^{0} \left[\left(-\frac{igAe^{ikx}}{\omega} \frac{Z_{I}(z)}{Z_{I}(0)} \right) \left(A_{I,I}^{(L)}e^{-ikx}Z_{I}(z) \right) \right]_{x=-\infty} dz$$

$$= \frac{-2i\rho gAkhA_{I,I}^{(L)}}{Z_{I}(0)}$$
(A7)

For the excitation volume flux $F_e^{(4)}$, using the free surface boundary conditions of incident and diffracted potentials, its expression as given in Eq. (21) can be written as:

15
$$F_{e}^{(4)} = \int_{x_{R,2}}^{x_{L,3}} \frac{\partial (\Phi_{I} + \Phi_{D})}{\partial z} \Big|_{z=0} dx = -i\omega\rho \int_{x_{R,2}}^{x_{L,3}} (\Phi_{I} + \Phi_{D}) \frac{i\omega}{\rho g} \Big|_{z=0} dx.$$
(A8)

1 With the employment of the free surface boundary condition of $\Phi_{R}^{(4)}$ inside the OWC chamber,

2 i.e., Eq. (2), and Green's theorem to $\Phi_{\rm D}$ and $\Phi_{\rm R}^{(4)}$ in a similar way as given in Eq. (A3), we have

$$F_{e}^{(4)} = -i\omega\rho \int_{x_{R,2}}^{x_{L,3}} \left(\Phi_{I} + \Phi_{D} \right) \left(\frac{\partial \Phi_{R}^{(4)}}{\partial z} - \frac{\omega^{2}}{g} \Phi_{R}^{(4)} \right) \bigg|_{z=0} dx$$

$$= -i\omega\rho \int_{x_{R,2}}^{x_{L,3}} \left(\Phi_{I} \frac{\partial \Phi_{R}^{(4)}}{\partial z} - \Phi_{R}^{(4)} \frac{\partial \Phi_{I}}{\partial z} \right) \bigg|_{z=0} dx$$
(A9)

3

8

- 4 For the unit normal at either water surface or wetted surface of structures in this paper is defined
- 5 pointing into the fluid region, thus for the mean water level inside the chamber, $\partial/\partial z = -\partial/\partial n$.

6 Using $\partial/\partial z = -\partial/\partial n$ at the mean water level and applying Green's theorem to $\Phi_{\rm I}$ and $\Phi_{\rm R}^{(4)}$, we 7 have

$$F_{e}^{(4)} = i\omega\rho \int_{x_{R,2}}^{x_{L,3}} \left(\Phi_{I} \frac{\partial \Phi_{R}^{(4)}}{\partial n} - \Phi_{R}^{(4)} \frac{\partial \Phi_{I}}{\partial n} \right) \bigg|_{z=0} dx = -i\omega\rho \int_{S_{\pm\infty}} \left(\Phi_{I} \frac{\partial \Phi_{R}^{(4)}}{\partial n} - \Phi_{R}^{(4)} \frac{\partial \Phi_{I}}{\partial n} \right) ds$$
$$= -i\omega\rho \left(-2ik \right) \int_{-h}^{0} \left[\left(-\frac{igAe^{ikx}}{\omega} \frac{Z_{I}(z)}{Z_{I}(0)} \right) \left(A_{I,I}^{(4)}e^{-ikx}Z_{I}(z) \right) \right] \bigg|_{x=-\infty} dz \qquad .(A10)$$
$$= \frac{2i\rho gAkhA_{I,I}^{(4)}}{Z_{I}(0)}$$
