We report concentrations of brominated flame retardants (BFRs) in 23 plastic samples from 20 new and second-hand children's toys sourced from the UK that had been previously shown to be Br-positive by XRF. The results reinforce existing evidence that the recycling of BFR-treated electronic plastics has led to the unintentional BFR contamination of articles not required to be flame-retarded. The principal BFRs detected were PBDEs (and in particular BDE-209), HBCDD and TBBP-A. PBDEs were detected in all samples with a maximum concentration of BDE-209 of 2500 mg/kg, and while TBBP-A was detected in 11 samples with a maximum concentration of 3100 mg/kg. HBCDD was detected in 14 cases and was present in four toys at concentrations (139-840 mg/kg) that would currently prevent their sale on the EU market. While estimated exposures to PBDEs via accidental ingestion of toy plastic fell well below USEPA reference doses, a child weighing 8.67 kg and ingesting 8 mg/day of a toy (the default assumption of the European Commission's Toy Safety Directive for scraped-off toy material) contaminated at our arithmetic mean concentration would be exposed to 0.2 ng/kg bw/day BDE-99. This compares closely to a health-based limit value (HBLV) proposed in The Netherlands of 0.23-0.30 ng/kg bw/day BDE-99. Of greater concern, the same child playing with a toy contaminated at the maximum concentration in this study would be exposed to 1.4 ng/kg bw/day BDE-99, thereby exceeding the HBLV. This paper is the first to consider BFR exposure via incidental ingestion of plastic from both contemporary and historical toys, revealing it to be considerable and for some children their most significant pathway of exposure.

recycled plastics; human exposure; POPs; PBDEs; HBCDD; TBBP-A

43

- 44 Highlights
- 45 Br and BFRs measured in children's plastic toys
- 46 HBCDD present in 4 toys at concentrations above the EU UTC limit value
- 47 PBDE concentrations in 2 toys exceed proposed limit of 500 mg/kg
- 48 TBBP-A detected in 11 samples
- 49 Children's exposure via unintentional ingestion of toy plastic may be substantial

### 1. INTRODUCTION

Due to evidence of their adverse health effects, brominated flame retardants (BFRs) such as polybrominated diphenyl ethers (PBDEs) and hexabromocyclododecane (HBCDD) are subject to global bans and restrictions. As a consequence, reports of the presence of BFRs in plastic children's toys as a result of the use of recycled polymers containing such chemicals are of concern (Chen et al., 2009; Ionas et al., 2014; DiGangi et al., 2017; Guzzonato et al., 2017; Puype et al., 2019; Straková and Petrlík, 2017). Children are particularly vulnerable to the adverse health effects of contaminants because of their behavioural tendencies (e.g., mouthing of objects and hand to mouth activities) that differ from adults and result in higher levels of exposure (Landrigan et al., 2011). To protect children from migratable substances in toys, the Toy Safety Directive (TSD) 2009/48/EC was introduced by the EU (European Commission, 2009). It stipulates that substances classified as carcinogenic, mutagenic, or toxic for reproduction (category 1A, 1B, or 2 and referred to as CMRs) shall not be used in toys or components thereof. While Br and BFRs are not specified under the TSD, in an effort to prevent the contamination of new plastic articles with PBDEs and HBCDD, the EU introduced low persistent organic pollutant (POP) concentration limits (LPCLs). Waste articles, such as plastic casings of end-of-life electronic equipment, that contain HBCDD or PBDEs present in the Penta- and Octa- (and, since 2019, Deca-) BDE formulations at concentrations exceeding the LPCL of 1,000 mg/kg cannot be recycled until their PBDE and HBCDD content has been destroyed or irreversibly transformed (European Commission, 2014; 2016). However, the LCPL is currently being reviewed with the aim of adopting legislative limits that are lower than 500 mg/kg as quickly as possible and no later than 2021 (European

Commission, 2019). Moreover, the EU has also introduced an Unintentional Trace Contaminant

(UTC) limit for HBCDD of 100 mg/kg (European Commission, 2016), with UTC limits for tetra-

76 , penta-, hexa-, hepta- and decaBDE of 10 mg/kg each to be introduced in July 2021 (European 77 Commission, 2019). 78 79 In addition to PBDEs and HBCDD, other BFRs have been used in a variety of applications to 80 impart flame retardancy to polymers such as electrical items and fabrics. The most widely used of 81 these is tetrabromobisphenol-A (TBBP-A) (Abdallah, 2016), while others such as 82 decabromodiphenyl ethane (DBPDE), pentabromobenzene (PBBz), hexabromobenzene (HBB), 83 pentabromotoluene (PBT), and pentabromoethylbenzene (PBEB) are also reported to have been 84 used (Covaci et al., 2011). As use of the latter five BFRs is thought to have increased in recent 85 years in response to restrictions on "legacy" BFRs like PBDEs and HBCDD, compounds such as 86 DBDPE, PBBz, HBB, PBT, and PBEB are collectively referred to here as "novel" BFRs (or 87 NBFRs). While TBBP-A and these NBFRs are not subject to restriction, their presence in, for 88 example, indoor air has been demonstrated (Abdallah et al., 2008; Cequier et al., 2014; Newton et 89 al., 2015), and concerns have emerged over their potential adverse health effects (Covaci et al., 90 2009; Nakari and Huhtala, 2009; Ezechiáš et al., 2012). Given the widespread use of such BFRs, 91 similar concerns exist that they may be present in items containing recycled plastics, with DBDPE 92 being reported to be present in children's plastic toys purchased in China (Chen et al., 2009). 93 94 Previously, 200 second-hand plastic toys (encompassing plastic components from multi-material 95 toys) sourced in the UK were analysed by X-ray fluorescence (XRF) spectrometry for the 96 presence of hazardous elements (As, Ba, Cd, Cr, Hg, Pb, Sb, Se) regulated in children toys under 97 the TSD, with Br as a proxy metric of BFRs also analysed and detected in many cases (Turner, 98 2018a). A subsequent study also found Br in many plastic toys that had been purchased new,

with the majority of Br-positive items black in colour and consistent with the recycling of

electronic waste plastic that is often black for cosmetic and economic purposes (Turner, 2018b).

99

The overall aim of this study, therefore, was to measure concentrations of various legacy (*i.e.* PBDEs and HBCDD) and NBFRs in a selection of toys sourced in the UK that had been shown to be Br-positive (Turner, 2018b), and to use these data to conduct an assessment of exposure of children playing with such toys and the associated health risk. As previous studies of this topic had not considered exposure via inadvertent ingestion of plastic particles, we further aimed to examine such exposure to test the hypothesis that this pathway is a significant source of exposure to infants. Subsidiary aims were to: (a) evaluate the extent to which measurements of elemental Br in toys are attributable to our target BFRs, and (b) identify any exceedances of the EU's current and impending LPCL and UTC limit values for PBDEs and HBCDD.

# 2. MATERIALS AND METHODS

112 2.1. Sampling and screening for total Br via XRF

Twenty three plastic components (samples) from 20 new and second-hand toys (Table 1) previously shown to contain Br that is believed to be derived in whole or in part from the recycling of electronic waste plastic (Turner, 2018a; 2018b) were selected for this study. Sample #s 4, 10, and 23 originated from new toys, with all other samples taken from second-hand items. Toys included game pieces, vehicles, parts of figures, items of jewellery and the handle of a dummy. As an additional check on the total Br content of each sample, and to assess the homogeneity of the distribution of Br, a NITON XL3t 700XRF spectrometer was used to make measurements at between two and four points on each sample (Table 1). Before analysis, the surface of each sample was wiped with a clean non-fibrillating tissue to remove any surface dust. The instrument window was then placed as flat as possible against the sample surface and a measurement of Br content conducted for 60 seconds. The limit of quantification for Br was 5 mg/kg. Calibration of the XRF was performed by Niton UK using proprietary standards

125	containing varying concentrations of relevant inorganic compounds in a polymer matrix. The
126	instrument was operated in a low density "plastics" mode and with thickness correction.
127	
128	2.2. BFR measurement methods
129	2.2.1. Chemicals and reagents
130	HPLC-grade solvents were used for sample extraction and LC-MS/MS analysis (Fisher
131	Scientific, Loughborough, UK). Concentrated sulphuric acid was purchased from Sigma-Aldrich
132	(St. Louis, MA, USA). Individual $\alpha$ -, $\beta$ - and $\gamma$ -HBCDD standards, $^{13}C_{12}$ $\alpha$ -, $\beta$ - and $\gamma$ -HBCDD,
133	d <sub>18</sub> -γ-HBCDD, individual standards of PBDEs 17, 28, 47, 49, 77, 99, 100, 153, 154, 183,196,
134	197, 209 and 128, ${}^{13}C_{12}$ -BDE-209, TBBP-A, ${}^{13}C_{12}$ -TBBP-A, PBBz, PBT, PBEB, HBB, and ${}^{13}C_{6}$ -
135	HBB and DBDPE were purchased from Wellington Laboratories (Guelph, ON, Canada).
136	Polychlorinated biphenyl (PCB)-129 was obtained from Qmx laboratories (Thaxted, UK). A
137	certified reference material (CRM) for polypropylene (ERM-EC591), containing certified
138	concentrations of PBDEs, was purchased from IRMM (Brussels, Belgium).
139	
140	2.2.2. BFR extraction and extract purification
141	Samples were analysed for concentrations of BFRs using a validated in-house method (Abdallah
142	et al., 2017). Briefly, accurately weighed 0.2 g aliquots of each sample where Br was detected by
143	XRF were transferred into 15 mL glass centrifuge tubes and spiked with 20 ng of internal
144	standards ( $^{13}C_{12}\alpha$ -, $\beta$ - and $\gamma$ -HBCDD, $^{13}C_{12}$ -BDE 77, $^{13}C_{12}$ -BDE-128, $^{13}C_{12}$ -TBBP-A and $^{13}C_{6}$ -
145	HBB) as well as 40 ng $^{13}$ C <sub>12</sub> -BDE 209. Samples were extracted with 3 mL CH <sub>2</sub> Cl <sub>2</sub> by vortexing
146	for 2 min and sonicating for 5 min. This was repeated with two further 3 mL aliquots of fresh
147	CH <sub>2</sub> Cl <sub>2</sub> . Extracts were collected and combined in a separate centrifuge tube and evaporated to
148	near dryness at 40 °C under a gentle stream of nitrogen before being reconstituted in 2 mL of
149	hexane and vortexed to precipitate dissolved plastics. The hexane supernatant was collected and

150	washed with 2 mL of >98 % concentrated sulphuric acid before vortexing for 30 s. Samples
151	were left for 2 h followed by centrifugation at 3000 rpm for 5 min to ensure complete separation
152	of the organic layer. The clean supernatant hexane layer was collected in a glass tube and
153	concentrated to near dryness before reconstitution in 200 $\mu L$ of toluene containing 0.1 $ng/\mu L$
154	PCB-129 and d <sub>18</sub> -γ-HBCDD for recovery determination (or syringe) standards. The extracts were
155	transferred to auto-sampler vials with glass inserts for quantitative analysis of PBDEs, PBBz,
156	and DBDPE on GC/MS. After GC-MS analysis, the same extracts were solvent-exchanged to
157	methanol ready for determination of HBCDDs and TBBP-A via LC-MS/MS.
158	
159	2.2.3. Instrumental Analysis
160	Determination of PBDEs and NBFRs was conducted on a ThermoFisher Trace 1310 gas
161	chromatograph coupled to a ThermoFisher ISQ mass spectrometer operated in electron
162	ionization mode and using selective ion monitoring. With a programmable temperature
163	vaporizer, 1 $\mu L$ of extracts were injected onto a Restek Rxi-5Sil MS column (15 m $\times$ 0.25 mm $\times$
164	$0.25~\mu m$ film thickness) with He as the carrier gas at a flow rate of 1.5 mL/min (Abdallah et al.,
165	2017).
166	
167	HBCDDs and TBBP-A were quantified on a Shimadzu LC-20AB prominence binary pump
168	liquid chromatograph equipped with a SIL-20A auto-sampler, and a DGU-20A3 vacuum
169	degasser coupled to an AB Sciex API 2000 triple quadrupole MS (Abdallah et al., 2017). An
170	Agilent Pursuit XRS3 C18 column (150 mm $\times$ 2 mm id, 3 $\mu$ m particle size) eluted with a mobile
171	phase of (i) 1:1 methanol/water with 2 mM ammonium acetate and (ii) methanol at a flow rate of
172	$180~\mu\text{L/min}$ . The mass spectrometer was operated in negative ESI mode. MS/MS detection
173	operated in the multiple reaction monitoring mode was used for quantitative determination of
174	HBCDD isomers based on $m/z$ 640.6 $\rightarrow$ 79, $m/z$ 652.4 $\rightarrow$ 79, and $m/z$ 657.7 $\rightarrow$ 79 for the native,

 $^{13}$ C-labelled and d<sub>18</sub>-labelled HBCD diastereomers, respectively and m/z 540.8 → 79, m/z175 176 552.8→79 for the native and <sup>13</sup>C-labelled TBBP-A, respectively. 177 178 2.2.4. *QA/QC* 179 Average recoveries of internal standards were between 65 % and 78 %. Table SI-1 shows that 180 the concentrations of PBDEs detected in an aliquot of the certified reference material ERM-181 EC591 compared favourably with the certified values. Limits of quantification (LOQs) were 182 estimated from a signal to noise ratio of 10:1; target compounds were not detected above LOQs 183 in the blanks and results were therefore not corrected for blank residues. Table SI-2 gives the 184 LOQs for all target compounds. 185 186 2.3. Data analysis For the purposes of calculating descriptive statistics, <LOQ values were replaced by fx LOQ, 187 188 where f = the detection frequency of a given BFR expressed as a decimal fraction. 189 190 2.4. Exposure estimation methods 191 2.4.1. Exposure via oral ingestion 192 Exposure via oral ingestion (E<sub>oral ingestion</sub> in ng/kg body weight/day) was estimated using the 193 following algorithm:  $E_{\text{oral ingestion}} = C_{\text{toy}} \times m \times (BA/BW)$ 194 195 where  $C_{\text{toy}}$  is the BFR concentration in the toy (in ng/g), m is the mass of toy ingested per day 196 which, by default, is 8 mg/day according to the Toy Safety Directive (Lenzner et al., 2018), BA is 197 the bioavailability of the BFR (%), assumed conservatively to equal the bioaccessibility of BFRs 198 of dust in simulated gastrointestinal tract fluid (Abdallah et al., 2012), and BW is body weight 199 (kg).

200	
201	2.4.2. Exposure via dermal uptake
202	We estimated exposure via dermal uptake ( $E_{\text{dermal}}$ in ng/kg body weight/day) as follows:
203	$E_{ m dermal} = C_{ m toy}^* \times PSA \times IEF \times (AF/BW)$
204	Here, $C_{\text{toy}}^*$ is the BFR concentration of BFR in toy the (in ng/m <sup>2</sup> ) ( $C_{\text{toy}}^* = 1.4 \times 0.05 \times C_{\text{toy}}$
205	assuming a 0.05 cm depth of surface and a density of 1.4 g/cm <sup>3</sup> equivlent to acrylonitrile
206	butadiene styrene) (Kuang et al., 2018), PSA is the palm surface area exposed dermally to the toy
207	(assumed to be $0.0986 \text{ m}^2$ ) (Chen et al., 2009), <i>IEF</i> is the indoor exposure fraction, or the
208	number of hours per day for which dermal contact with toys occurs (assumed to be 2; Chen et al.,
209	2009), and $AF$ is the absorbed fraction. The latter is based on measured data for the dermal
210	uptake of PBDEs and HBCDD from fabrics over a 24 h contact (Abdallah and Harrad, 2018) and
211	measured data for 24 h contact with solutions of TBBP-A (Abdallah et al., 2015), and is
212	normalised for a 2 h period.
213	
214	3. RESULTS AND DISCUSSION
215	3.1. Concentrations of Br and BFRs in children's plastic toys
216	Table 2 reports the average of the replicate measurements of total Br made by XRF for each toy,
217	including components thereof, while Table SI-3 lists each individual Br measurement for these
218	samples. In some cases, total Br appears to be uniformly distributed in the plastic, while in other
219	cases there is evidence for its heterogeneous dispersion in the toy. Table 2 also lists
220	concentrations of the target BFRs in each sample, as well as the median, arithmetic mean, and
221	maximum concentrations for the whole dataset.
222	
223	BFRs were detected in all toys tested with summed concentrations ranging from 1.4 mg/kg to
224	about 6140 mg/kg. The principal BFRs detected in the toys were either PBDEs (in particular

BDE-209), HBCDD or TBBP-A, with only low concentrations detected of our target NBFRs.

The newest toys, purchased in 2017, contained < 20 mg/kg of BFRs but displayed a wide range in compounds historical and new BFRs. Overall, the BFR pattern and absolute concentrations in our samples are within the range of those previously reported for other studies of plastic items containing recycled polymers, including toys and food contact articles (Chen et al., 2009; Guzzonato et al., 2017; Ionas et al., 2014; Kuang et al., 2018; Puype et al., 2015, 2017). If our study has quantified all of the Br-containing compounds in a sample, then the total Br and ΣBFR concentrations should be broadly equal, with the latter slightly exceeding the former because Br only constitutes a proportion of the mass of any BFR. Moreover, as we measured BFRs in a single small aliquot of each toy or component thereof and our replicate XRF measurements of Br revealed varying degrees of inhomogeneity of Br distribution within the sample, Br and ΣBFR measurements will deviate in some instances. Specifically, the heterogeneous distribution of Br and BFRs likely explains why ΣBFRs > average Br in sample #s  $5 (\Sigma BFRs = 847 \text{ mg/kg c.f. Br} = 90 \text{ mg/kg}) \text{ and } 6 (\Sigma BFRs = 468 \text{ mg/kg c.f. Br} = 289 \text{ mg/kg});$ thus, in sample #5, while Br was <LOQ at 2 measurement points, it was 269 mg/kg at a third, and in sample #6, while Br was <LOQ at 1 measurement point, it was 578 mg/kg in the other. Conversely, where Br exceeds \( \Sigma BFR \) substantially for a given sample (e.g., sub-samples #15, 16 and 17 from the same toy) this implies that there is another source or sources of Br in that sample. This may either be an organobromine compound, like the NBFR, BTBPE, which was not measured here but was detected at 1,100 mg/kg in a UK plastic kitchen utensil (Kuang et al., 2018), a polymeric BFR (Gouteux et al, 2008; Puype et al, 2017) or an inorganic Br compound. Despite these discrepancies, however, there was a significant relationship between Br and ΣBFR among the samples, with linear regression analysis returning a best fit line of Br =  $1.39 \Sigma BFR +$  $208 (r^2 = 0.840, p < 0.05).$

248

249

251	3.2. Do concentrations of PBDEs and HBCDD in toys exceed LPCL and/or UTC limit values?
252	Two of the samples analysed (#s 2 and 8) exceed the proposed LPCL value of 500 mg/kg for the
253	summed concentrations of PBDEs (including Deca-BDE), and three additional samples (#s 6, 18
254	and 20) exceed the UTC limit set for July 2021 of 10 mg/kg for Deca-BDE alone. With regard to
255	HBCDD, four samples (#s 2, 5, 11 and 12) exceed the UTC limit of 100 mg/kg, although all
256	were purchased before the limit was introduced (March 2016). Overall, eight out of the 23 sub-
257	samples analysed exceed current or impending limit values for restricted BFRs. In all cases, the
258	items exceeding limits were second-hand and manufactured before 2016. This may suggest that
259	measures to eliminate BFRs from toys containing recycled plastic have been effective; however,
260	we only studied three toys manufactured after these measures were introduced and a much larger
261	study is required to fully evaluate the efficacy of these measures.
262	
263	A recent report revealed the presence of HBCDD in various toys and Rubik's cubes purchased in
264	the Czech Republic, up to a maximum of 91 mg/kg in a toy shoe (Straková et al., 2017). Of even
265	greater concern, an earlier survey of 95 Rubik's cubes and 16 additional child-related items
266	sourced from 26 countries around the world (DiGangi et al., 2017) revealed a maximum HBCDD
267	concentration of 1,586 mg/kg, with two items exceeding the LPCL value at the time of 1,000
268	mg/kg and seven exceeding the UTC limit value of 100 mg/kg.
269	
270	3.3. The presence of TBBP-A and NBFRs in toys
271	Relatively few reports exist of the presence of BFRs other than PBDEs and HBCDD in plastic
272	toys, and we believe this study to be only the second report of TBBP-A in such products. Our
273	data for concentrations of TBBP-A (range not detected to 3,140 mg/kg) suggest a broadly similar
274	level of contamination to that observed in toys from the Czech Republic, Germany, and Italy
275	(range 210 mg/kg – 7,800 mg/kg) (Guzzonato et al., 2017). Only trace quantities of the target

276 NBFRs were detected in our samples, providing reassurance that their presence in plastic toys is 277 not currently of significant concern. 278 279 3.4. What are the human exposure implications of the presence of BFRs in toys? 280 The potential for human exposure arising from the presence of PBDEs in toys has previously 281 been evaluated (Chen et al., 2009; Ionas et al., 2014). These studies identified potential for 282 exposure via inhalation arising from volatilization of PBDEs, mouthing, dermal contact and oral 283 ingestion (transfer of PBDEs to hands and subsequent oral exposure). As both studies employed 284 the same exposure assessment algorithms, the relative importance of the four exposure pathways 285 was identical in both instances. In summary, exposure via mouthing was estimated to 286 predominate for pre-school children, with exposures via the other pathways making relatively 287 minor contributions. While the absolute estimated exposure levels varied due to the differences 288 in BFR concentrations in toys between the two studies, neither study identified exposures via 289 contact with toys to be of significant toxicological concern. 290 291 Detailed examination of the input data employed to estimate exposure via inhalation, dermal 292 contact, and oral ingestion (Chen et al., 2009; Ionas et al., 2014) reveals the key input parameter 293 in each case to be an emission factor derived for volatilization of PBDEs from flame-retarded 294 items like television sets (Kemmlein et al., 2003). While constituting a useful approach to 295 scoping exposure via these pathways, volatilization emission factors from source items 296 containing PBDEs at concentrations well in excess of those present in plastic toys are predicted 297 to overestimate inhalation exposures and are less appropriate when extrapolated to the estimation 298 of dermal and oral ingestion pathways. Similar considerations apply to the volatilization

emission factors reported previously (Kemmlein et al., 2003) for HBCDD (for which the

emission factors are from flame-retarded expanded and extruded polystyrene), while published

299

emission factors for TBBP-A and DBDPE do not appear to be available (Kemmlein et al., 2003)
Regarding mouthing exposure, Chen et al. (2009) based their estimates on experimentally-
derived measurements of BFR migration from two toy samples into human saliva. However, the
data obtained are expressed as pg/cm <sup>2</sup> /minute rather than as a proportion of the BFR mass
present in these toys and cannot thus be extrapolated to estimate migration from toys containing
different BFR concentrations such as ours. More recently, exposure to a variety of organic
contaminants (but not BFRs) present in plastic children's toys has been evaluated, based on
inadvertent oral ingestion of small quantities of plastic and subsequent uptake via the
gastrointestinal tract (Lenzner et al., 2018).
Given the aforementioned considerations, we evaluate for the first time exposure to BFRs
measured in plastic children's toys for: (a) the oral ingestion of 8 mg/day of toy plastic (in line
with the default assumption of the Toy Safety Directive for scrapable toy material), and (b)
dermal uptake arising from a child handling toys. As Chen et al. (2009) identified infants aged
between 3 and 18 months (and of body weight 8.67 kg) to be at greatest risk, we have evaluated
exposure for this age group only.
Table 3 summarizes our estimates of typical and high-end exposure via both pathways identified
above ( $E_{\text{oral ingestion}}$ and $E_{\text{dermal}}$ ) and obtained using both the arithmetic mean and the maximum
BFR concentrations, respectively, for the samples shown in Table 2. It is very clear that while
dermal exposure does occur for young children, exposure arising from accidental ingestion of
plastic from toys is orders of magnitude greater. Also shown in Table 2 are previously published
typical and high-end exposure estimates to BFRs for UK children arising from other pathways;
namely: diet (Tao et al, 2017), inhalation (Tao et al, 2016), dust ingestion (Tao et al, 2016),
dermal contact with BFR-containing fabrics and indoor dust (Abdallah and Harrad, 2018), and

326	breast milk consumption (Tao et al, 2017). Typical and high-end estimates arising from each
327	pathway for $\Sigma PBDEs$ and $\Sigma HBCDDs$ are also compared in Figures 1 and 2, respectively.
328	
329	It is evident that exposure via incidental oral ingestion of toy plastic can make a very substantial
330	contribution to overall exposure of young children to our target BFRs. Specifically, under the
331	typical scenarios (where the plastic ingested is assumed to contain BFRs at the arithmetic mean
332	concentration determined in this study, along with typical estimates for other pathways),
333	ingestion contributes 31.8 % of overall exposure to $\Sigma PBDEs$ and 58 % of overall exposure to
334	$\Sigma$ HBCDD. Under the high-end exposure scenarios (where the plastic ingested is assumed to
335	contain the maximum BFR concentration determined, along with high-end estimates for other
336	pathways), the contribution made by ingestion of toy plastic to overall exposure falls to 17.7 %
337	and 41 % of ΣPBDEs and ΣHBCDD, respectively.
338	
339	We also compared exposures to PBDEs via oral ingestion of and dermal uptake from plastic toys
340	with the reference doses (RfDs) promulgated by the USEPA for BDEs 47 and 99 (= 100 ng/kg
341	bw/day) and BDE 209 (= 7,000 ng/kg bw/day) (US EPA, 2019a; 2019b; 2019c). Reassuringly,
342	even under the maximum exposure scenario estimated exposures arising from toys alone or the
343	combined pathways are well below the respective RfD values. However, our maximum exposure
344	estimate arising from toys alone for BDE-99 (1.4 ng/kg bw/d) exceeds the health-based limit
345	value (HBLV) proposed in the Netherlands (Bakker et al., 2008) of 0.23-0.30 ng/kg bw/day.
346	Moreover, the typical exposure estimate from toys (0.2 ng/kg bw/day) is very close to this
347	HBLV.
348	

350	This study provides the first evidence of the presence of a range of BFRs in both new and
351	second-hand toys sourced from the UK. These data add to previous evidence from elsewhere in
352	the world that suggest that recycling of BFR-treated plastics has led to the unintentional but
353	widespread contamination of articles not required to meet flame retardancy regulations. Eight out
354	of the twenty plastic toys examined contained concentrations of PBDEs or HBCDD that would
355	now or in the near future prevent their sale on the EU market. Exposure of young children to
356	BFRs via incidental ingestion of plastic from toys has also been evaluated for the first time.
357	Exposure via this route appears to be considerable and for some individuals and BFRs may
358	represent the most significant pathway via which they are exposed.
359	
360	SUPPORTING INFORMATION
361	Tables showing: (1) concentrations of PBDEs detected in a certified reference material compared
362	to certified values, (2) limits of quantification for target BFRs, and (3) concentrations of total Br
363	detected in replicate measurements made for each toy.
364

<sup>&</sup>lt;LOQ denotes not detected

<sup>&</sup>lt;sup>a</sup> for purposes of calculating descriptive statistics, where concentration <LOQ the value has been replaced with fx LOQ where f = detection frequency of BFR expressed as a decimal fraction

 $<sup>^{</sup>b}$  Low POP Concentration Limit for  $\Sigma PBDEs$  – to be enforced from 2021

<sup>&</sup>lt;sup>c</sup> Unintentional Trace Contaminant limit value for BDE-209 – to be enforced from 2021

<sup>&</sup>lt;sup>d</sup> Unintentional Trace Contaminant limit value for HBCDD – current since 2016

Table 3: Estimated exposures (ng/kg bw/day) to BFRs of young children associated with plastic toys and other pathways

Exposure pathway/scenario	BDE- 47	BDE- 99	BDE- 209	ΣPBDEs	ΣHBCDD	ΣNBFRs
E <sub>oral ingestion</sub> (typical) <sup>a</sup>	0.2	0.2	21	35	64	0.0001
Eoral ingestion	1.3	1.4	318	520	634	160
(high-end) <sup>a</sup>						
$E_{\text{dermal}} \text{ (typical)}^{\text{b}}$	0.001	0.001	-i	0.01	0.2	_i
$E_{\text{dermal}}$ (high-end) <sup>b</sup>	0.007	0.006	-i	0.092	2.0	i -
Diet (typical) <sup>c</sup>	nr	nr	nr	4.8	1.0	3.0
Diet (high-end) <sup>c</sup>	nr	nr	nr	26	6.2	19
Breast milk (typical) <sup>d</sup>	17	5.9	0.65	35	17	18
Breast milk (high-end) <sup>d</sup>	41	10	2.8	80	34	350
Dermal contact with dust and	nr	nr	ز	3.9	24	ز
fabrics <sup>e</sup>						
Indoor air inhalation and dust	0.10	0.17	31	33	2.9	32
ingestion (typical) <sup>f</sup>						
Indoor air inhalation and dust	18	28	2200	2300	870	290
ingestion (high-end) <sup>f</sup>						
$RfD^g$	100	100	7000	-	-	-
HBLV <sup>h</sup>	-	0.23-	-	-	_	-
		0.30				

<sup>&</sup>lt;sup>a</sup> assuming that child ingests 8 mg day<sup>-1</sup> of toy plastic contaminated at arithmetic mean and maximum concentration for "typical" and high-end exposure

<sup>&</sup>lt;sup>b</sup> assuming that dermal contact occurs with toys contaminated at the arithmetic mean and maximum concentration for "typical" and high-end exposure

<sup>&</sup>lt;sup>c</sup> "typical" and high-end dietary exposures for UK toddlers (Tao et al., 2017)

d "typical" and high-end exposures for breast-fed UK infants (Tao et al., 2017)

<sup>&</sup>lt;sup>e</sup> sum of exposures via dermal contact with indoor dust and BFR-containing fabrics (Abdallah and Harrad, 2018). Note ΣPBDE exposure for this estimate covers only those congeners present in the Penta-BDE formulation detected in a fabric covering from a US sofa

f sum of estimates of exposure of UK toddlers via indoor air inhalation and dust ingestion (Tao et al., 2016). For dust ingestion, "typical" exposure assumes median BFR concentration and mean dust ingestion, high-end exposure assumes 95<sup>th</sup> percentile BFR concentration and high dust ingestion.

<sup>&</sup>lt;sup>g</sup> USEPA Reference dose (US EPA, 2019a; 2019b; 2019c)

<sup>&</sup>lt;sup>h</sup> Health based limit value proposed by Bakker et al. (2008)

<sup>&</sup>lt;sup>i</sup> dermal absorption not detected for BDE-209 and not studied for our target NBFRs nr = not reported

Figure 1: Relative contribution (expressed as %of total exposure) of selected pathways to exposure of UK young children to \$\times PBDEs\$ under (a) typical and (b) high-end scenarios (note no high-end estimate available of dermal exposure via dust and fabrics)

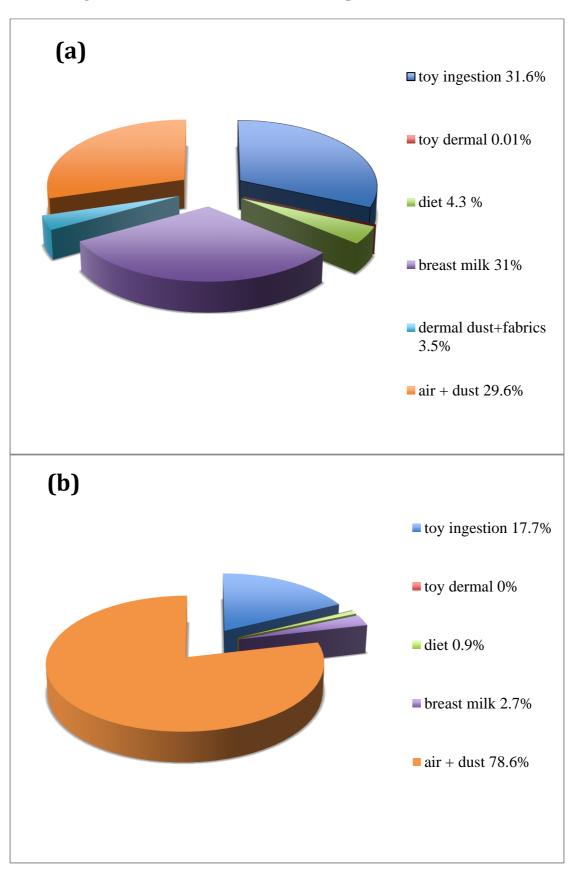

Figure 2: Relative contribution (expressed as %of total exposure) of selected pathways to exposure of UK young children to ΣHBCDD under (a) typical and (b) high-end scenarios (note no high-end estimate available of dermal exposure via dust and fabrics)
