Appendix A – Kern method

The following sections present the Kern method calculations used in this paper with Figure 28 outlining the calculation process. This example calculation uses values from the 0.5Lmin^{-1} case. Appendix D summarises the geometric input values used throughout the calculations. Taborek and Spalding (1983) presented the initial method.

The method is outlined in the following way:

- First table – Definition of new known variables
- Second table – Definition of new unknown variables
- Third table – Calculation process for new unknown variables

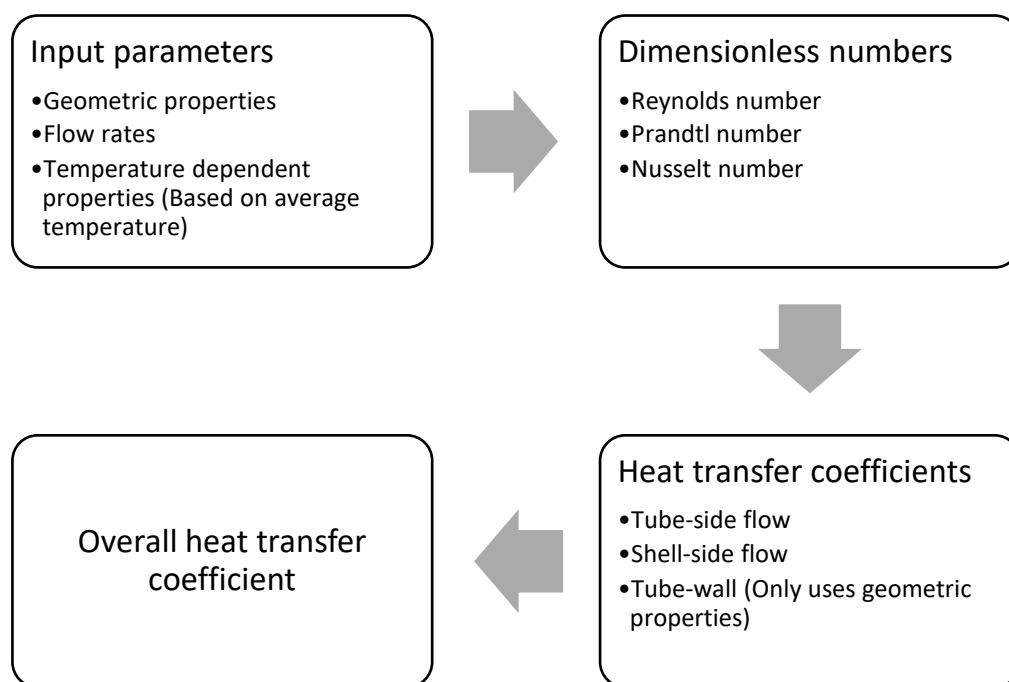

Figure 1: Process outlining the Kern method

Temperature dependent variables polynomial functions

As values for the temperature dependent variables were needed for all calculations water property tables were sourced from a wide range of literature. This data was then plotted to allowing curve fit equations to be determined. The equations are presented below where the input temperature have the units of degree Celsius ($^{\circ}\text{C}$).

Density:

$$\rho = -((8.554 \times 10^{-8})T^4) + ((3.055 \times 10^{-5})T^3) - ((6.657 \times 10^{-3})T^2) + ((2.967 \times 10^{-2})T) + 999.88$$

Dynamic viscosity:

$$\mu = ((2.831 \times 10^{-15})T^6) - ((1.224 \times 10^{-12})T^5) + ((2.201 \times 10^{-10})T^4) - ((2.186 \times 10^{-8})T^3) + ((1.368 \times 10^{-6})T^2) - ((5.915 \times 10^{-5})T) + 1.783 \times 10^{-3}$$

Specific heat capacity at constant pressure:

$$C_p = -((3.541 \times 10^{-11})T^5) + ((1.203 \times 10^{-8})T^4) - ((1.559 \times 10^{-6})T^3) + ((1.037 \times 10^{-4})T^2) - ((3.283 \times 10^{-3})T) + 4.217$$

Thermal conductivity:

$$\lambda = ((1.945 \times 10^{-8})T^3) - ((1.098 \times 10^{-5})T^2) + ((2.051 \times 10^{-3})T) + 5.655 \times 10^{-1}$$

Temperature dependent variables

For the shell and tube flow the temperature dependent variables were determined based on average inlet and outlet temperatures from the experimental results. As the calculation does not specify heat exchanger configuration the temperature values were an average of both configurations. Wall temperature was approximated using the average of the shell and tube side temperatures.

Appendix B – Bell-Delaware method

Within this section an example calculation of the Bell-Delaware method is carried out. This was applied to the UHX geometry. Initially global parameters are determined and then flow rate specific calculations. For this example, the calculations are for the 0.5Lmin^{-1} case. Figure 29 presents an overview of the parameters used within the Bell-Delaware method. Here the Reynolds number specific correction factors and non-Reynolds specific correction factors have been outlined. Figure 30 shows the calculation steps to determine the overall heat transfer coefficient and the subsequent variables used to determine it.

Bundle bypass correction factor

As the value for Reynolds number was less than 100 the value of the bundle bypass correction factor coefficient was set at 1.35 as per the specification in the outlining document. For the 2 and 3Lmin⁻¹ calculation this value was decreased to 1.25 as the value of the Reynolds number increased above 100. As no sealing strips are used the ratio of sealing strips to number of effective tube rows crossed between baffle tips, r_{ss} , is 0.

^aExpression used to relate temperature and specific heat (Appendix D)

^bEquation uses wall temperature of 450K

Equation 1

(Holman, 2010)

$$U = \frac{\dot{Q}}{A\Delta T_{ln}}$$

Where:

\dot{Q} – Rate of heat transfer (W)

U – Overall heat transfer coefficient (Wm⁻²K⁻¹)

A – Heat transfer area (m²)

ΔT_{ln} – Log mean temperature difference (K)

Equation 2

(Rogers, 1992)

$$\dot{Q} = \dot{m}C_p\Delta T$$

Where:

\dot{Q} – Rate of heat transfer (W)

\dot{m} – Mass flow rate (kgs⁻¹)

C_p – Specific heat capacity at constant pressure (Jkg⁻¹K⁻¹)

ΔT – Temperature difference (K)

Equation 7

$$\Delta T_{ln, val} = \frac{(T_w - T_o) - (T_w - T_i)}{\ln\left(\frac{T_w - T_o}{T_w - T_i}\right)}$$

Where:

ΔT_{ln} – Log mean temperature difference (K)

T_w – Tube wall temperature (K)

T_o – Shell outlet temperature (K)

T_i – Shell inlet temperature (K)

Experimental method

Parallel-Flow Experiment

1. Set the UHX for parallel flow and set the heat tank temperature to 60°C
2. Set the tube flow rate to 3Lmin⁻¹
3. Start-up flow of shell water and using the hand operated flow control valve, set the flow rate to 0.5Lmin⁻¹
4. Allow the system to attain a steady state. This may need at least five minutes and you may need to adjust the flow control valve slightly to keep flow rate constant
5. Record tube and shell circuit temperatures
6. Repeat the procedure for the shell flow rates of 1, 2 and 3Lmin⁻¹

Counter-Flow Experiment

1. Reconfigure the heat exchanger for counter flow and repeat the parallel-flow experimental process

Experimental results

Results from five data sets were analysed with outliers omitted allowing the average temperature profile to be determined (Table 23 and Table 24)

CFD input parameters

Mesh settings

All standard settings are the same as the validation case. A face meshing is being used on the tube ends to promote the isothermal surfaces. The shell volume was meshed using the 14.53 million settings specified above.
