A B S T R A C T

Objective: The aim of this article is to describe this systematic and phased process in developing the evidence-based ‘Exercise and Depression Toolkit’ for health care providers working with adults with depression.

Methods: The Appraisal of Guidelines, Research and Evaluation (AGREE) II tool was consulted throughout the developmental phased process, and used to guide toolkit content and dissemination strategies. The four phases included a review of relevant literature, formative interviews, an expert panel meeting, and finally toolkit development. A Theoretical Domains Framework (TDF) analysis was also used to determine behaviour change techniques (BCT) to be included in the toolkit. Various stakeholders were involved throughout the process including health care providers, adults who have lived experience with depression, researchers, and exercise professionals who have experience working with adults with depression.

Results: Recommendations from the consultation process included that the toolkit be ‘depression tailored’ including specific barriers that adults with depression face to engaging in physical activity (PA) and strategies they can use. The toolkit should promote collaboration and a person-centered approach. Different parts of the toolkit should be created for the intended audience of health care providers and adults with depression. BCTs were included to target the ‘Emotion’ and ‘Social Influences’ domains of the TDF.

Conclusions: These recommendations have resulted in the development of the ‘Exercise and Depression Toolkit’. This toolkit is a resource for health care providers, adults with depression, and exercise professionals to help exercise become an accessible treatment option for the many Canadians living with depression.

1. Background

Depression affects over 300 million people worldwide and its prevalence has increased significantly since 2005 (WHO, 2019). It is one of the leading causes of disability in Canada and globally (MHCC, 2013; WHO, 2019), and Canada’s national burden has been estimated to be more than that of lung, prostate, breast and colorectal cancers combined (Ratnasingham, Cairney, Rehm, Manson, & Kurdyak, 2012). Depression can be debilitating with symptoms such as hopelessness, despair, and thoughts of death greatly impacting individuals, families and communities and placing significant burden on economies and health care systems. There is an urgent need to develop innovative and
acceptable treatment options that are accessible to individuals with depression.

Systematic reviews have consistently shown structured exercise programs to significantly reduce depressive symptoms for individuals with depression (e.g., Cooney et al., 2013; Josephson et al., 2014; Krogh, Hjorth, Speyer, Gluud, & Nordenfelt, 2017; Schuch et al., 2016a). The most recent meta-analysis of 11 randomized controlled trials examined the antidepressant effects of exercise among adults (18–65 years) recruited through mental health services with a referral or clinical diagnosis of major depression (Morres et al., 2019). Analyses demonstrated a large significant overall antidepressant effect ($g = -0.79$). In light of such evidence, depression is the first and only mental health disorder in which exercise is recommended as an evidence-based treatment in clinical guidelines.

Physical activity (PA) is defined as any bodily movement produced by skeletal muscles that results in energy expenditure (Caspersen, Powell, & Christenson, 1985). Exercise is a subset of PA and is defined as PA that is planned, structured, repetitive, and done for the purposes of improving or maintaining physical fitness (Caspersen et al., 1985). The National Institute of Clinical Care and Excellence in the United Kingdom recommends exercise as a treatment for subthreshold and mild-moderate depression (National Collaborating Centre for Mental Health UK, 2009). The American Psychiatric Association acknowledges that exercise can be used as a monotherapy for mild depression in the acute phase after a diagnosis with monitoring of mood by a health professional (APA, 2010). More recently, the Canadian Network for Mood and Anxiety Treatments (CANMAT) revised its treatment guidelines and now recommends exercise as a primary intervention for mild-moderate Major Depressive Disorder (MDD), and as an adjunctive treatment for moderate-severe MDD (Ravindran et al., 2016). Throughout this manuscript, the use of the term depression refers to MDD. CANMAT recommends a ‘dose’ of exercise based on the best available evidence acknowledging that personal fitness and current and past activity levels also be considered. This ‘dose’ is 2–3 times a week for a duration of 30 minutes at a moderate intensity for a minimum of 9 weeks. Supervised exercise is recommended for adherence, and either cardiovascular or resistance training can be used (Ravindran et al., 2016). The CANMAT guideline is of significance as this is the first time that exercise has been recommended as a monotherapy for depression in Canada.

1.1. Physical Activity Guidelines, treatment guidelines and clinical populations

In Canada, little structure exists for mental health professionals to explore exercise as a treatment option for adults with depression. Clinical treatment guidelines such as the CANMAT guidelines were developed to help health care providers implement evidence-based research into their clinical practice (Ravindran et al., 2016). However, releasing guidelines or providing education about guidelines are not sufficient to elicit behaviour change (Pederson et al., 2017). Guidelines help to understand ‘what’ to do, but not ‘how’ to do it (implementation). It is likely that most mental health care professionals in Canada have not received any training in exercise or PA promotion, similarly, many exercise professionals may not have been exposed to mental health training (Faulkner, 2016). Accordingly, there is a need to develop resources to support health care professionals in implementing the CANMAT guidelines and to consider exercise as an antidepressant treatment option with clients. While further consideration is needed in how best to support adults with depression to start and maintain exercise as an intervention for their depression, we have assumed that the starting point is initial treatment planning with a clinician.

Work has been done to facilitate the implementation of guidelines for other clinical populations. The seminal international Physical Activity Guidelines (PAGs) for adults with chronic spinal cord injuries were released in 2011 (Martin Ginis et al., 2011). After release of these PAGs, a working group used a systematic process to develop an evidence-informed spinal cord injury specific resource to supplement the guidelines and support behaviour change, the ‘SCI Get Fit Toolkit’ (Arbour-Nicitopoulos et al., 2013; SCI Action Canada, 2013). The process described by Arbour-Nicitopoulos et al. (2013) served as a template in developing a similar resource to be used by clinicians for implementing the CANMAT guidelines.

The aim of this article is to describe this systematic and phased process used to develop the evidence-based ‘Exercise and Depression Toolkit’ for health care providers working with adults with depression. The four phases included: a review of relevant literature, formative interviews, an expert panel meeting, and final toolkit development. Various stakeholders were involved throughout the process including health care providers, adults who have lived experience with depression, researchers, and exercise professionals. The next sections will further describe each of these four phases in detail.

2. Methods and results

2.1. Overview

The Agree II instrument is a tool used to develop quality evidence-based guidelines, ensuring methodological rigour and transparency (Brouwers et al., 2010; Agree II, 2017). It has also been used for resource development and health promotion (Arbour-Nicitopoulos et al., 2013; Latimer-Cheung et al., 2013). The AGREE II was consulted throughout the developmental process and used to guide toolkit content and dissemination strategies. Similar to past use of the AGREE II for resource development, modifications were made to items for health promotion and resource development rather than guideline development. The project leads (KG & GF) consulted the third author (KAN) on use of the AGREE II and for appraisal of the included items. KAN was the AGREE II expert for this project given her leadership on the development and pilot-testing of the SCI Get Fit Toolkit. Table 1 outlines all AGREE II items and modifications, as well as application to the Exercise and Depression Toolkit (referred to throughout this paper as the ‘toolkit’). Fig. 1 provides a summary of the events and timeline leading to the development of the toolkit.

2.2. Toolkit development process

2.2.1. Phase one: review of the literature

Before development of the toolkit, the evidence-base reviewed by KG and GF included the CANMAT guidelines (Lam et al., 2016; Ravindran et al., 2016) and recent meta-analyses on exercise for clinical depression (e.g., Krogh et al., 2017; Schuch et al., 2016a; 2016b). Two scoping reviews were also conducted to provide a framework for comprehensively understanding barriers and facilitators to clinician and client participation in PA and exercise promotion, respectively (Glownacki, Duncan, Gainforth & Faulkner, 2017; Glownacki, Weatherston, & Faulkner, 2019). A behavioural analysis driven by theory was used in both reviews using the Theoretical Domains Framework (TDF; Kane, O’Connor, & Michie, 2012). The TDF is part of a larger meta-framework, known as the Behaviour Change Wheel, which helps intervention developers select behaviour change techniques (BCTs) (Cane, Richardson, Johnston, Ladha, & Michie, 2015; Michie et al., 2013; Michie & Atkins, 2014). Behaviour change techniques are the active ingredients within an intervention (what can be observed and replicated) designed to change behaviour (Michie & Atkins, 2014). Thus, conducting a TDF analysis was done to theoretically inform the content of the toolkit.

The first review included thirteen studies that reported on barriers and facilitators to PA and exercise participation among individuals with depression using quantitative, qualitative or mixed methods (Glownacki et al., 2017). To meet inclusion criteria, articles were also required to be peer reviewed, English language, include sample populations of adults

<tr>
<td>1) The overall objective(s) of the guideline is (are) specified.</td>
<td>The overall objective of the toolkit is specifically described.</td>
<td>To support health care professionals in collaborating with clients to explore exercise as a treatment option for adults with mild-moderate depression.</td>
</tr>
<tr>
<td>2) The health question covered by the guideline is specifically described.</td>
<td>The practical questions covered by the toolkit are specifically described.</td>
<td>What type of resource(s) will support health care professionals to discuss exercise as a treatment for mild-moderate depression with clients? What type of resource will motivate adults with depression to consider exercise as a treatment option?</td>
</tr>
<tr>
<td>3) The population to whom the guideline is meant to apply is specifically described.</td>
<td>The population to whom the toolkit is targeted towards is specifically described.</td>
<td>Adults diagnosed with mild-moderate depression aged 18-65 in Canada not meeting the recommended 150 min per week of moderate-vigorous PA per week.</td>
</tr>
<tr>
<td>Domain 2- Stakeholder Involvement: consideration of the views of the target group(s) and their representation within the recommendations development group.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4) The guideline development group includes individuals from all relevant professional groups.</td>
<td>The expert panel includes individuals from all relevant professional groups.</td>
<td>Experts in depression, physical activity, knowledge translation; representatives from mental health &amp; physical activity organizations; health care providers; individuals with lived experience with depression; researchers.</td>
</tr>
<tr>
<td>5) The views and preferences of the target population have been described.</td>
<td>Original AGREE II item retained.</td>
<td>Panel included end users of the toolkit and the population the toolkit is targeting. Formative research was done through interviews with adults with depression and health care providers.</td>
</tr>
<tr>
<td>6) The target users of the guideline are clearly defined.</td>
<td>The target users of the toolkit are clearly defined.</td>
<td>Health care organizations and providers that work with adults with depression, inclusive of (but not limited to): Family Physicians, Psychiatrists, Counsellors, Mental health workers, Occupational Therapists, Recreation Therapists, Nurses, Social workers.</td>
</tr>
<tr>
<td>Domain 3- Rigour of development: methods and criteria used to inform the recommendations, the review process, and plans for updating.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7) Systematic methods were used to search for evidence.</td>
<td>Original AGREE II item retained.</td>
<td>Research evidence purposefully selected including CANMAT Guidelines (Ravindran et al., 2016) and scoping reviews on barriers and facilitators for AWD and HCP (Glowacki et al., 2017; 2019).</td>
</tr>
<tr>
<td>8) The criteria for selecting the evidence are clearly described.</td>
<td>Original AGREE II item retained.</td>
<td>Criteria are described in the methods section of this paper and in scoping reviews (Glowacki et al., 2017; 2019) and CANMAT guidelines (Ravindran et al., 2016).</td>
</tr>
<tr>
<td>9) The strengths and limitations of the body of evidence are clearly described.</td>
<td>Original AGREE II item retained.</td>
<td>Key strengths include use of a theory-driven analysis to determine BCTs (Cane et al., 2015; Glowacki et al., 2019, 2017) and the rigorous process to attain the highest level of evidence (one) to support exercise for MDD (Ravindran et al., 2016). Key limitations include varying methods of diagnosis of depression (Glowacki et al., 2017), no separation of terms PA or exercise (Glowacki et al., 2017, 2019), and lack of long-term data to support exercise for MDD (Ravindran et al., 2016). Further details provided in the methods section and in the discussion of the scoping reviews (Glowacki et al., 2017, 2019) and CANMAT guidelines (Ravindran et al., 2016).</td>
</tr>
<tr>
<td>10) The methods for formulating the recommendations are clearly described.</td>
<td>Original AGREE II item retained.</td>
<td>A multistep process used in previous PA toolkit development work in adults with SCI was applied (Arbour-Nicitopoulos et al., 2013): 1. Review of evidence by panel participants before the meeting; 2. Summary of key points from the evidence-base; 3. Structured working groups/breakout sessions; and 4. Review of final content and recommendations by panel survey and feedback.</td>
</tr>
<tr>
<td>11) The health benefits, side effects and risks have been considered in formulating the recommendations.</td>
<td>The practical implications have been considered in developing the toolkit.</td>
<td>The toolkit increases awareness and knowledge of the CANMAT guidelines, common barriers and strategies to help individuals with depression engage in exercise &amp; PA are identified; an advocacy tool for improving access to exercise as a treatment for depression; a link to an exercise screening tool is provided; varying programming and exercise referral schemes across Canada and demand may increase; extra training on the toolkit may be needed.</td>
</tr>
<tr>
<td>12) There is an explicit link between the recommendations and the supporting evidence.</td>
<td>Original AGREE II item retained.</td>
<td>Toolkit content and format recommendations were reviewed and revised by panel experts and CANMAT board members.</td>
</tr>
<tr>
<td>13) The guideline has been externally reviewed by experts before its publication.</td>
<td>The toolkit has been externally reviewed by experts before its publication.</td>
<td>The online toolkit will be updated according to resources available.</td>
</tr>
<tr>
<td>14) A procedure for updating the guideline is provided.</td>
<td>A procedure for updating the toolkit is provided.</td>
<td>Recommendations are considered clear based on feedback from the expert panel (see Table 5). Different options for management are considered clear based on feedback from expert panel (see Table 5), and CHOICE-D (Parikh et al., 2018) document is referenced for further details. Recommendations are considered easily identifiable based on feedback from the expert panel (see Table 5).</td>
</tr>
<tr>
<td>Domain 4- Clarity of presentation: transparency of the recommendations and dissemination options</td>
<td></td>
<td></td>
</tr>
<tr>
<td>15) The recommendations are specific and unambiguous.</td>
<td>Original AGREE II item retained.</td>
<td>Recommendations are considered clear based on feedback from the expert panel (see Table 5).</td>

(continued on next page)
18) The guideline describes facilitators and barriers to its application.

Facilitators and barriers to dissemination of the toolkit were discussed.

19) The guideline provides advice and/or tools on how the recommendations can be put into practice.

The recommendations provide advice and/or tools on how the toolkit can be put into practice.

20) The potential resource implications of applying the recommendations have been considered.

The potential resource implications of disseminating the toolkit have been considered.

21) The guideline presents monitoring and/or auditing criteria.

Strategies for monitoring and/or auditing the uptake of the toolkit have been considered.

Domain 6: Editorial independence: independence of the recommendations from the views of the funding body and competing interests of the expert panel.

The views of the funding body have not influenced the content of the guideline.

Facilitators and barriers are outlined in the Discussion. Key facilitators include: identifying champions in different sectors, partnering with organizations with a large following (e.g. CANMAT and Centre for Active Living), and creation of social media packages to give to champions and organizations. Key barriers include: extra training on the toolkit may be needed, and may be multiple parts to the toolkit that will need to be packaged together.

Ensuring HCP can readily distinguish the credibility of the information; instructions on use of the toolkit in practice included in the ‘INTRO’ document; additional supplementary materials as handouts for clients. Website management and hosting; personnel available to update website and track downloads; and greater demand for resources, programs and staff.

Monitoring of online downloads of the toolkit (number of downloads and reach) and planned formal feedback on its use in practice through ongoing evaluation.

Key strengths of the two scoping reviews include the use of a theory-driven analysis to determine BCTs (Glowacki et al., 2017; 2019; Cane et al., 2015). Furthermore, a key strength of the CANMAT guidelines includes the rigorous process used to reach a consensus on the highest level of evidence (level one: meta-analysis with narrow confidence intervals and/or two or more RCTs with adequate sample size, preferably placebo controlled plus clinical support) to support exercise as a treatment for MDD (Ravindran et al., 2016).

Key limitations of the scoping reviews include the exclusion of grey literature or articles in a language other than English (Glowacki et al., 2017; 2019), varying methods of diagnosis of depression (Glowacki et al., 2017), and the terms PA and exercise often being used interchangeably (Glowacki et al., 2017; 2019), even though CANMAT guidelines specify exercise as a treatment recommendation. Key limitations of the CANMAT guidelines are more reflective of the state of the exercise and depression evidence base. For example, there remains a lack of long-term data on the benefits of exercise for MDD, and less evidence regarding effectiveness in clinical practice (Ravindran et al., 2016).

2.2.2. Phase two: formative research

This phase of the project was approved by the University of British Columbia Institutional Ethics Review Board. Semi-structured interviews were conducted with the toolkit’s target population of Canadian adults with a self-reported diagnosis of depression from a health care provider (n = 13). Diagnosis was not confirmed by chart review or speaking to a health professional. However, participants were screened and asked whether they had been diagnosed with depression, by whom (which health care provider), and in what practice setting (e.g. family physician in primary care). Interviews were also conducted with potential end users of the toolkit, a variety of Canadian health care providers who have experience working with adults with depression (n = 14). Interviews identified needs, content and format preferences for the toolkit. See Table 2 for demographic characteristics of the participants.

Overall, participants (adults with depression and health care providers) reported the CANMAT guidelines to be acceptable. They identified that they had previous knowledge that exercise was beneficial for depression, but that they had not necessarily known it was recommended as a primary treatment. Some clarification was desired on the definition of exercise, and how much exercise was recommended as...
a treatment. Participants felt it was important to know the “FITT” principles, which is the frequency, intensity, time, and type of exercise, to aim for if exercise was going to be used or recommended as a treatment for depression. Participants also wanted the toolkit to include self-monitoring resources such as a mood and activity diary, and for it to highlight health and other benefits of engaging in PA. Participants requested the content of the toolkit be ‘depression tailored’, including a section on the specific barriers that adults with depression face in engaging in PA, strategies for overcoming barriers, and stories or experiences from individuals with depression about their beneficial participation in PA. Lastly, people wanted a resource that could be used collaboratively by a health care provider and an individual with depression in considering exercise as a treatment for depression. All health care providers (n = 14) and the majority of individuals with depression (n = 7) wanted to be able to access the resource online. The second most desired format was paper (n = 5 individuals with depression; n = 9 health care providers). Considering these preferences, the panel agreed that the toolkit will be available online as a downloadable PDF to either be used online or printed and used as a paper copy as desired.

2.2.3. Phase three: expert panel meeting

A multidisciplinary panel of twelve experts comprised of PA and mental health researchers, health care providers, adults with lived experience with depression, and exercise professionals that have experience working with adults with depression appraised the evidence from phases one and two to generate content, format and dissemination recommendations for the toolkit. See Table 3 for the full list of panel members, affiliations, and roles.

2.3. Scope and purpose of the toolkit

Prior to the expert panel meeting, the first author provided the panel with an executive summary of the results from the two scoping reviews and the interviews that were part of phases one and two. This was done one month in advance of the meeting to provide the panel adequate time to review and consider in relation to the entire toolkit project. At the beginning of the meeting, a summary of the project’s

* AWD = Adult with Depression, HCP = Health Care Provider, MVPA = Moderate-Vigorous Physical Activity.

† Two participants were medical residents at the time of interview and reported working full-time and being a student full-time.

‡ AWD = Adult with Depression, HCP = Health Care Provider, MVPA = Moderate-Vigorous Physical Activity.

Objective: To support health care professionals in collaborating with clients to explore exercise as a treatment option for adults (aged 18–65) with mild-moderate depression.

Target Population: Adults diagnosed with mild-moderate depression aged 18–65 in Canada not meeting the recommended 150 min per week of moderate-vigorous PA per week.

End Users: Health care providers who work with adults with depression, inclusive of (but not limited to): Family Physicians, Psychiatrists, Counsellors, Mental Health Workers, Occupational Therapists, Recreation Therapists, Nurses, and Social workers. Community, Primary Care, Inpatient, and Outpatient settings.

Panel members split into two working groups and participated in five, 45–60 min breakout sessions. Topics of these sessions included: Review of draft content and structure of the toolkit; Facilitate decision-making around exercise as a treatment option; Addressing barriers; Look and feel of the toolkit; Dissemination. Content and format recommendations were then developed by the panel as an entire group using the evidence reviewed before the meeting (see Table 4). A debriefing meeting was held at the end of the first day between the project leads and one expert panel member (KAN) to summarize these recommendations. On the second day, a facilitated discussion (lead by the project leads KG and GF) was held with the entire group to review and revise recommendations.

2.3.1. Phase four: toolkit development

The toolkit content was written by the first author (KG) in collaboration with the second author (GF) based on the panel meeting recommendations and the desired content identified from the formative interviews with adults with depression and health care providers in phase two. It was decided by KG and GF that there would be three parts to the toolkit (see supplementary file for the first part). The first part is the ‘Introduction’ document created for the target audience (end user) of health care providers. This document explains the process used for toolkit development, relevant literature, and gives instructions and recommendations on how to use the toolkit. Creation of this document was guided by the second scoping review (Glowacki et al., 2019) and the salient barriers to promoting physical activity identified by health care providers. This document is to address any pessimism regarding clients’ motivation to exercise, and build the self-efficacy of health care providers to discuss and recommend exercise by informing them of the evidence-base used to create the toolkit, and the inclusion of tools and behaviour change techniques to help clients overcome barriers to PA and exercise. An example of a recommended BCT for health care providers included in this document is ‘Persuasion to boost self-efficacy’.

The second part of the toolkit is the ‘Collaboration’ document for a clinician and client to use together (pg. 1–4). An important part of developing this content was the ordering of these pages. KG and GF determined the ordering based on an anticipated collaborative treatment decision-making process. The first author (KG) works as a mental health occupational therapist and used clinical reasoning as guidance for the ordering of this section’s content. This begins with a discussion of ‘Why exercise?’ in comparison to other treatment options and why it may be a good fit for an individual (pg. 1). This page also includes the desired content of highlighting various benefits of exercise. This then leads to a discussion about someone’s personal experiences with exercise or PA in the past, and the incorporation of behavioural activation and the mood cycles in and out of depression (pg. 2 ‘How are exercise and depression related?’). These mood cycles are to be used as an educational tool and are the recommended BCT of ‘information about emotional consequences’ (Cane et al., 2015) and are central to the toolkit. The conversation continues to a discussion about if exercise will be used as a treatment, how much exercise is recommended based on the CANMAT guidelines (pg. 3 ‘CANMAT Guidelines at a glance’). This page has the desired content of what the guidelines are, specifying the frequency, intensity, time and type of exercise to aim for if using exercise as a treatment. The conversation then leads to the discussion of common barriers or concerns that individuals with depression may face when engaging in PA on page 4 ‘Moving More’. Possible actions (behaviour change techniques) to address or overcome these concerns are also included. The content of this page is guided by the first scoping review and TDF analysis (Glowacki et al., 2017). The page has an endpoint, in which a collaborative decision is made to either refer to an exercise program, engage in further PA counselling to help increase general PA (either with the current health care provider or referral to another), or to think about exercise further and discuss at a later date.

The third part of the toolkit is the ‘Action Materials’ section, which is targeted to adults with depression. These materials are client handouts that can be given to an individual with depression by a health care
provider at their discretion, and then be used independently or in col-
aboration with their health care provider. These handouts are linked to
the collaborative pages and are the actions that
may include effects and ad-
aptation of the collaborative pages and are the actions that
may include... the wider spectrum of the toolkit (Glowacki et al., 2017).
For example, Handout #1, is a Mood and Activity Diary, which is the
recommended BCT of ‘Self-assessment of affective consequences’ (Cane
et al., 2015). This part of the toolkit also includes the desired content of
self-monitoring resources, and stories about positive personal experi-
ences that adults with depression have had with exercise.

After content was developed, the toolkit itself was then created in
collaboration with a graphic designer. Through online survey, members
of the expert panel were consulted to ensure that content and format
recommendations were appropriately addressed (as per discussions that
occurred during the panel meeting). Table 5 provides a summary of the
panel's feedback. Consistency was indicated between the panel rec-
ommendations and the general content and presentation of the toolkit.
Responses were favourable on all items (M = 6.42 on a 7-point scale).
Some suggestions by the panel were to provide information about other
treatment options, to change the wording of intro-

Expert panel for the toolkit recommendations development group.

3. Discussion
Our working group developed the first evidence-informed resource to
support health care professionals in collaborating with clients to
explore exercise as a treatment option for mild-moderate depression and
supplement CANMAT guidelines (Ravindran et al., 2016). This was
done following an internationally accepted and rigorous consultation
process (AGREE II, 2017), successfully used previously in another
clinical population (Arbour-Nicitopoulos et al., 2013).

Our working group faced some challenges in the process of develop-
oping the toolkit. Access to exercise referral schemes for depression is
fragmented in Canada. Systematic reviews suggest that effects and ad-
herence are better when exercise is supervised and structured (Stubbs
et al., 2016). Accordingly, the CANMAT guidelines refer to structured
and supervised exercise (Ravindran et al., 2016). However, such pro-
grams may not always be available. This impacted decisions that were
made by the panel regarding content of the toolkit (a greater focus on
exercise than habitual or lifestyle PA) and on the end point of the
toolkit and the decision making process, particularly if there was no
option for an exercise referral. While exercise referral may not always
be possible, the working group considers PA promotion as something
clinicians should be engaging in with their clients with depression.
However, it is acknowledged that increases in PA may not be sufficient
for an antidepressant effect but will provide other important health
benefits. It is important that health care providers, along with in-
dividuals with depression considering exercise as a treatment,

(continued on next page)
understand the difference between PA and exercise.

We also acknowledge that a toolkit by itself is likely insufficient in supporting behaviour change, particularly in terms of helping individuals start and maintain exercise as a treatment for mild-moderate depression. With successful and informed dissemination, this toolkit will help health care providers integrate evidence-based guidelines related to exercise and depression into their practice and will be a starting point to facilitate the decision-making process and consideration of exercise as a treatment for mild-moderate depression. For exercise to become an accessible and feasible treatment alternative integrated regularly in health service delivery, significant work is still needed. Mental health care providers will need some training on exercise and PA (Glowacki et al., 2019), and exercise professionals will need training on working with clients with depression (Faulkner & Biddle, 2001). Continued advocacy to key stakeholders such as government health authorities, decision makers, and community organizations is necessary for larger policy and organizational-level changes to support an exercise referral infrastructure for depression in Canada.

However, we believe the toolkit will serve different purposes for different stakeholders. For health care providers, the toolkit provides an evidence-based resource that can be used in practice to guide and facilitate conversations in considering exercise as a treatment for depression. It can also be used as a tool to facilitate PA promotion. For adults with depression, the toolkit is intended to increase awareness and knowledge of recommendations around exercise as a treatment for depression, and to provide behavioural strategies to overcome barriers for increasing PA and engaging in exercise. For exercise professionals, the toolkit can be used as an advocacy tool for integration of exercise programs and professionals into mental health care.

### 3.1. Dissemination barriers and facilitators

Now that the toolkit has been developed, attention has turned to disseminating the toolkit to clinicians nationally. Barriers to disseminating the toolkit need to be considered. The toolkit involves multiple components, so it will need to be marketed in one package. Extra training on the use of the toolkit may be needed for health care providers. Lastly, the targeted end users of the toolkit include a wide variety of different professions, and so dissemination may need to be tailored to each.

Facilitators that may help dissemination of the toolkit are to engage champions in different sectors including stakeholders involved in this development process, as well as work with our community partners to promote the toolkit (e.g., CANMAT, Centre for Active Living, and Canadian Mental Health Association). The creation of a social media package to send to partners will help them to disseminate through their own platforms and organizations. A tiered approach to national dissemination could start with the province of British Columbia where it was created and then move to other provinces. Housing of the toolkit will be done in one online location (www.exerciseanddepression.ca), so stakeholders promoting and disseminating the toolkit can use one website link with endorsement. This will also help to evaluate and track reach of the toolkit.

### 3.2. Strengths and limitations

A strength of this work is the thorough systematic process used to develop the toolkit through consultation of the Agree II instrument throughout the process to ensure quality, methodological rigour and transparency on how the toolkit was developed. This includes ensuring all six domains (and 23 items within the domains) were adequately addressed: scope and purpose, stakeholder involvement, rigour of development, clarity of presentation, applicability, and editorial independence. Table 4 explicitly outlines how all items and domains were addressed. Some examples of rigour of development (domain 3) include reviewing relevant literature and the two scoping reviews conducted (item 7 and 8), the multi-step phased process (item 10), and the consideration of practical implications for use of the toolkit by health care providers (item 11). Our group did not calculate a quality score by appraisers of each item. In replacement of this, a survey was sent back to panel members with their recommendations and the first draft of the toolkit to ensure that these were adequately met. Stakeholder involvement was an integral part of the process, and our group aimed for diversity of perspectives and expertise of the expert panel. This includes experts in depression, PA, knowledge translation, representatives from mental health and PA organizations, health care providers, individuals with lived experience with depression and researchers. Stakeholders including adults with depression and health care providers were consulted through the entire process reflecting an integrated knowledge translation approach for effective health promotion (Arbour-Nicitopoulou et al., 2013; Olsson, Skovdahl, & Engström, 2016).

### 3.3. Future directions

Panel members will work with community partners and organizations to disseminate the toolkit across the province of British Columbia, and across Canada. The project leads are planning to evaluate the use of the toolkit in practice. In particular, they plan to evaluate the acceptability of the intervention, perceived attributes of the innovation, and how this may influence dissemination and adoption. Evaluation will also be conducted on the uptake of the resource and its reach to the target audience once it is nationally disseminated and available online.

Additional funding will be sought for further dissemination and knowledge translation activities such as a development of educational sessions and educational training videos about using the toolkit and recommendations on its use.

4. Conclusion

Developing the Exercise and Depression Toolkit is the first step in bridging the gap between treatment guidelines for depression and the consideration of exercise as a treatment option in practice. Development followed an internationally accepted and rigorous consultation process by use of the AGREE II instrument (2017). Future evaluation is planned on the use of the toolkit in practice, and to monitor its uptake and reach once disseminated. In tandem with other evaluation is planned on the use of the toolkit in practice, and to consideration of exercise as a treatment option in practice.

4.5 Additional funding will be sought for further dissemination and knowledge translation activities such as a development of educational sessions and educational training videos about using the toolkit and recommendations on its use.

4. Conclusion

Developing the Exercise and Depression Toolkit is the first step in bridging the gap between treatment guidelines for depression and the consideration of exercise as a treatment option in practice. Development followed an internationally accepted and rigorous consultation process by use of the AGREE II instrument (2017). Future evaluation is planned on the use of the toolkit in practice, and to monitor its uptake and reach once disseminated. In tandem with other advocacy and research initiatives, it is anticipated that the toolkit will help health care providers integrate evidence-based guidelines into their practice related to exercise and depression. It is also anticipated that this will be a starting point in helping exercise become an accessible treatment option that is integrated into health service delivery to improve the lives of the many Canadians living with depression.
