Abstract

The biomedical research complex has been estimated to consume almost a quarter of a trillion dollars every year. Unfortunately, there is evidence that a high proportion of this sum is avoidably wasted. Last year the *Lancet* published a series of 5 papers showing how dividends from the investment in research might be increased from the relevance and priorities of the questions being asked, to how the research is designed, conducted, and reported. Seventeen recommendations were addressed to five main stakeholders - funders, regulators, journals, academic institutions, and researchers. This paper provides some initial observations on the possible impacts of the series. It appears to have provoked several important discussions and has appeared on the agendas of several key players. There are also examples of individual initiatives illustrating ways of reducing waste and increasing value in biomedical research. This momentum is likely to move more strongly across stakeholder groups, if more collaborative relationships evolve among key players; more important work is required to increase research value. A forthcoming meeting in Edinburgh will provide a forum within which to foster the collaboration needed.

Introduction

More than 30 years ago the adverse clinical consequences of biased under- reporting of research were clearly documented ¹, and non-publication remains hugely problematic. ²⁻⁵ Non-publication is bad value for funders, who could double research output by ensuring all the studies they fund are published, and it puts patients and clinicians at a substantial disadvantage in making informed decisions about healthcare. ⁶ Trial registration, supported by the International Committee of Medical Editors (ICMJE)⁷, has helped^{8,9} although it is clearly not a panacea. ^{10,11} Other related initiatives, such as the Alltrials initiative (www.alltrials.net) and the Institute of Medicine's recent report on data sharing ¹² are working to ensure that the results of all trials are reported and their data made available.

Non-publication was one of four contributors to the estimated 85% of current research funding that Chalmers and Glasziou suggested in 2009 were being avoidably "wasted" across the entire biomedical research spectrum (e.g., clinical, health services, and basic science). Evidence of the degree and avoidability of waste in research production at each of their 4-stage model (see Figure 1) has strengthened: imbalenced research question selection, poor study design^{14,15} and execution, non-publication¹⁶ and poor reporting¹⁷. In addition to 295 citations, the 2009 paper led the National Institute of Health Research (NIHR) in England to establish a working group to monitor and plan actions, with regular meetings and an annual closed conference. Their "Adding Value in Research" programme added an additional stage aiming to ensure that NIHR funded research: 1. addresses questions relevant to clinicians, patients and the public; 2. uses appropriate design and methods; 3. is delivered efficiently; 4. results in accessible full publication; and 5. produces unbiased and usable reports. They developed a quality improvement tool¹⁸ for these 5 stages to identify common themes and examples of good practice across their programmes. For example, since 2013, NIHR has required applicants for support of new primary research should reference an existing systematic

review "as well as including reference to any relevant literature published subsequent to that systematic review" or where no such systematic review exists applicants should undertake to review the relevant evidence (using a methodology that systematically identifies, critically appraises and then synthesises the available evidence) which "must also include reference to relevant on-going studies, e.g. from trial registries".¹⁹

Last year the *Lancet* published a series of articles ("Increasing value: reducing waste") extending the 2009 analysis to 50 journal pages, with over 40 authors²⁰⁻²⁴ focused on the 5 NIHR stages (see Figure 1). As the commissioning editors noted "Our belief is that research funders, scientific societies, school and university teachers, professional medical associations, and scientific publishers (and their editors) can use this Series as an opportunity to examine more forensically why they are doing what they do ... and whether they are getting the most value for the time and money invested in science.".²⁵

The series, and an accompanying symposium²⁶, provided a voluminous body of evidence of the problems in biomedical research, along with 17 recommendations (see Table 1) to help increase its value, covering funders, regulators, journals, academic institutions, and researchers. The problems include (although they are not limited to) whether planned research met the needs of end users.²⁷⁻²⁹

Initial media attention included coverage by several newspapers including the leading German paper Der Spiegel³⁰, although there has been almost no response from German researchers or organizations.³¹ Several research funders responded through meetings, working parties, and some changes of processes (see Funders section below). In the year since their publication the five articles have been downloaded 46,596 times from the Lancet.com and Science Direct.com websites. The five articles have already been cited 113 times (Scopus); were all in the top 5% of all articles indexed by Scopus; and their Altmetric scores (social media) all ranked above the 98th percentile (of more

than 3 million articles scored) including 589 tweets (about 20% of which were by healthcare professionals).

This follow-up paper offers an overview of the initial influence of the series. Prior to conducting the assessment a protocol was developed outlining the key players, the methods of our investigation, including sampling frames (see Panel 1 with more detail in Appendix 1). The primary focus was to examine what funders, regulators, journals, academic institutions, and researchers are doing, and plan to do, to address waste in biomedical research.

Funders

A few funders have already responded to the series. In May 2014, The French Institute of Health and Medical Research INSERM (Institut National de la Santé et de la Recherche Médicale), in conjunction with the EQ

UATOR network, organised a 1-day conference in Paris on "Improving reporting to decrease the waste of research" with the head of the Wellcome Trust and NIHR's HTA programme among the speakers (video of all sessions is available on the EQUATOR website.³² The series was included in recent discussions of INSERM's strategic plan for 2016-2020, and was presented at the annual meeting of INSERM team leaders.³³ In Australia, the National Health and Medical Research Council (NHMRC) set up a working party to review all the recommendations in the series³⁴, updating and modifying their procedures, and also featured an opening session on "Adding Value, Reducing Waste" at their 2014 annual scientific meeting³⁵ The series was also on the agenda of the Heads of International Research Organizations (HIRO) group's meeting in 2014.

We are also heartened that concern about poor replicability and quality of much animal and other preclinical research³⁶ has prompted some influential organisations to draw attention to and

address these concerns. For example, a meeting on 'Reproducibility and reliability of biomedical research' was convened jointly by the UK Academy of Medical Sciences, the UK Medical Research Council, the Wellcome Trust and the Biotechnology and Biological Sciences Research Council. The National Centre for the Replacement, Refinement and Reduction of Animals in Research (www.nc3rs.org.uk) has supported three international meetings (in Nijmegen, Edinburgh and Washington DC) on systematic reviews of animal research, and this year held an international meeting on biased under-reporting of animal research³⁷, bringing together several relevant groups targeted in the series. Whether or not the Lancet series had any role in these initiatives, they are very welcome.

The examination of the funder's websites (see Methods panel) indicates that most funders are not explicit about many of the key issues, making it challenging to evaluate them. The NIHR had a number of innovative and exemplary features, such as requirements for systematic reviews before embarking on additional primary studies, active monitoring of ongoing studies, and its own journal. For other funders, the picture was more mixed (see Table 2). Most required trial registration, but few required systematic reviews prior to additional primary studies, or mentioned reporting guidelines, such as CONSORT, or the EQUATOR Network. Regarding conduct of systematic reviews before additional primary research, most funding organisations only required systematic reviews before considering funding future clinical trials. NIHR was an exception in that they ask for a systematic review for any research projects being submitted to them (see Table 1; 3rd recommendation from series). Only two of these funders had a substantial targeted research scheme that addressed priority questions for clinicians and patients: the NIHR's Health Technology Assessment program, and the Patient-Centered Outcomes Research Institute (PCORI) in the United States.

To maximize research value funders may want to consider ways to enhance their funding priorities in line with existing (regional, national, and international) priority setting initiatives (See Table 1; 2nd recommendation). Similarly, funders may want to enhance efforts to ensure that wherever possible protocols are developed using relevant guidance, such as SPIRIT for randomized trials and PRISMA-P for systematic reviews (see: www.equator-network.org/), and that the research they fund is registered in a relevant repository (e.g., World Health Organization's International Clinical Trials Registry Platform - http://www.who.int/ictrp/en/, and PROSPERO) (See Table 1; 4th recommendation). For example, a review of 75 recently funded randomized trial protocols at one granting agency showed they often did not provide adequate information about allocation sequence generation (13% missing) and concealment (19% missing): important characteristics of well conducted randomized trials. Funders could also consider stronger policies to support (guidance, education, and infrastructure) and enforce (incentives and penalties) publication of all research, open access, and data sharing.

Regulators

Regulators can help here by not providing ethics approval of protocols that are scientifically inadequate. Research proposals that are scientifically poor are, by definition, ethically inadequate. For example, the guidance for researchers issued by the newly established Health Research Authority (HRA) ³⁹ in the UK now states "Any project should build on a review of current knowledge. Replication to check the validity of previous research is justified, but unnecessary duplication is unethical."

On the other hand, research regulators can reduce waste resulting from inefficiencies in research regulation. Some of these result from hyper-regulation of low risk non-interventionist research, such as many descriptive surveys. Following a report⁴⁰ from the Academy of Medical

Sciences in the UK, the HRA is now addressing this problem. As a result, proportionate measures of assessing research proposals have been introduced that take account of the plausible risks associated with the research proposals being considered.

Some research regulators have also taken steps to reduce the problem of biased under-reporting of research (see Table 1; 14th recommendation). In the UK, a favourable ethics opinion for proposed clinical trials will not now be granted unless the proposed trial has been registered publicly.⁴¹ Following pressure from the Alltrials campaign, the European Medicines Agency has now committed to make available all clinical study reports (see Table 1; 5th and 13th recommendations) of research leading to marketing licences for new drugs.⁴²

Journals

Given that more than half of the reports of clinical trials do not set their results in the context of the totality of evidence²⁴, journals have much work to do to improve this situation. They can achieve this by providing specific guidance on their websites about this crucial feature and providing similar guidance to peer reviewers. In response to the series, the Lancet strengthened its requirement to put research into context (see Table 1; 3rd recommendation).⁴³ From the beginning of this year, all research papers submitted to any journal in the Lancet family must include a 'Research in context' panel. The editors expressed their "hope that increasing the prominence of putting research into context in the submission and publication stages will help researchers, institutions and funders make decisions earlier in the process on which research questions to address and fund.".

Other journals have made similar efforts, such as panels asking authors 'what this paper adds'.

Based on our interviews with journals editors (see Methods panel) the Lancet series has been an impetus for reflection and change among some editors. It has been discussed internally during inhouse editorial meetings, at an editorial board retreat of one journal and is on the agenda for discussions with other editorial boards. The series has also been on the agenda of the influential editorial groups, such as ICMJE, along with other ongoing initiatives, such as the Institute of Medicine's recent report on data sharing. Some journals have already acted on the series. For example, PLoS Medicine commissioned an editorial on how open access can reduce waste. Other concurrent initiatives focused on reducing research waste, not directly attributable to the series, are also underway. For example, a large group of rehabilitation medicine editors signed up collectively to mandate the use of reporting guidelines in their journals. This policy is likely to introduce a strong incentive to prospective authors across this content area to use reporting guidelines. Other fields are starting to implement similar strong guidance.

The results of examining the journals websites (see Methods panel) indicates there is wide variability of information contained on journal websites and the language used across journals (see Figure 2). This is likely to confuse prospective authors, particularly those early on in their research careers and those whose first language is not English. While journals want to maintain their uniqueness, and emphasize particular issues important to them, it might be useful to consider some items, perhaps particularly those related to the recommendations in the series, as core information, and unambiguous language that could be included across all journal websites. This might help improve matters for journals, prospective authors, and readers.

One immediate goal could be for every journal to explicitly support use of reporting guidelines (see Table 1; 17th recommendation). The evidence indicates that their use is associated with increases in the completeness of reporting clinical trials.⁴⁸ Approximately half of the websites

mentioned reporting guidelines which is a similar proportion to that reported by Hirst and Altman in 2012.⁴⁹ Far fewer journal websites explicitly mentioned the EQUATOR Network and few mentioned the use of systematic reviews in the context of reporting the main results of their research (see Table 1; 3rd recommendation).

Journals can also add value to their websites by explicitly asking authors to provide more information about their methods particularly the interventions used or details of participants. For example, few (11%) reports from a sample of 255 cancer trials provided sufficient information about the interventions studied⁵⁰ to allow clinicians to use the results in practice.⁵¹ Across the 10 questions used to assess the websites the results did not vary substantially by journal impact factor (< 5; ≥ 5).

Academic Institutions

We are aware of very little explicit attention by academic institutions to the Lancet series.

One exception has been in Iran, where a group of academics are running a series of workshops on the Lancet series. Two workshops on "Biomedical research: increasing value, reducing waste' were run in February 2015 for Directors of Clinical Research Centers, research vice chancellors, and Director Generals of Research Affairs of Medical Universities of North West Universities of Iran. A final national workshop is planned for the research deputies of all 50 Medical Universities of Iran. ⁵²

Based on our e-mail survey (see Methods panel) we received complete responses from only 26 of the 100 invited universities. We found that most (n=20) schools have a policy to register clinical trials in a publically accessible trial registry and to make full study reports available (n=19), but such policies are rare for protocols (n=5), analytical algorithms (n=5), and raw data (n=5). Two of the 26 universities indicated not having an institutional policy for any of these five elements (see Table 1; e.g., 12th and 14th recommendations).

Only five medical schools reported having a policy to make all study protocols publically available. At Duke University, for example, "all approved study protocols are available through the School of Medicine's electronic IRB [Institutional Review Board] pathway", but such a repository for study protocols seems rare elsewhere. In contrast, prospective registration of clinical trials in a publically accessible trial register is enforced by almost all institutions we surveyed. Although registration appears common among 'top' institutions, the extent to which this policy happens across less prestigious academic institutions is unclear. Trial registration has been required by the ICMJE since 2005⁷, and also some governmental institutions, such as FDA in the US, require registration of all clinical trials. Despite these policies, only about half of all published trials are currently being registered. At Duke University "registration at ClinicalTrials.gov is required before IRB approval, and registration record completion is required before IRB close-out". These examples highlight the importance of regulation to help maximize best research practice.

Up to half of all initiated clinical trials remain unpublished.⁵⁵ The Food and Drug Administration (FDA), in the United States, requires posting of clinical trial results in ClinicalTrials.gov within one year after study completion, but this is done for less than a quarter of trials falling within FDA's mandatory reporting rules⁵⁶, possibly due to lack of enforcement. This indicates the important role of universities in further enforcing the publication of all trial results. The majority of the responding deans said they have a policy to make publically available full publications of studies performed at their institution (see Table 1; 17th recommendation). The University of Sydney is currently in the final stages of establishing an open access policy which "will make publications available whenever copyright/archiving policies allow through its external access repository, no later than 12 months after the date of publication. Where access to the full text of collected scholarly works is not permitted by the publisher, publication of metadata and a link to the published work will be made openly available". At the University of Groningen, "full publications

are typically published in its final version in the University Repository and thus largely publically available".

Policies to make raw data and analytical algorithms publically available seem much rarer, although individual universities show promising initiatives (see Table 1; 5th and 14th recommendations). The University of Sydney has a "research data registry and Electronic Lab Notebook platform, both of which enable the publication of metadata (i.e., data about data - data that describes and gives information about other data) and data sets". It states that "Researchers should make completed research data sets openly available for re-use by other researchers, unless this is prevented by the requirements of legislation or University policy, or ethical, contractual or confidentially obligations. If open access is not possible due to legal or policy reasons, researchers should make metadata openly available".

Other universities have less explicit policies. Cambridge University, in the United Kingdom, for example, explicitly "encourages researchers to be as open as possible in discussing work with other researchers and with the public. Once results have been published, the University expects researchers to make available relevant data and materials to other researchers, on request". At the University of Bristol, "researchers can make study protocols, raw data and analytical algorithms publically available at the institutional data repository". Beyond the stated policies there is no data on whether and how the universities monitor the implementation of any of these policies.

The slow uptake of some of the recommendations by academic instructions is unfortunate, as a considerable proportion of all biomedical research resources go to universities⁵⁷. One explanation may be the fact that university policies on these issues are rarely defined on a nationwide or even global level, making it difficult to coordinate policies. This can be illustrated by the large variety in the surveyed universities' policies to make study materials publically available.

Researchers

Motivated by the principle that it is unethical, unscientific, and wasteful to embark on research without systematically reviewing evidence of what is already known, particularly when the research involves people or animals, three Scandinavian researchers⁵⁸ convened and inaugurated an international Evidence-Based Research (EBR) Network at the end of 2014. The EBR Network will urge funders, regulators, researchers, academic institutions, and journals to implement the changes needed to promote evidence-based research. Initiatives such as Trial Forge⁵⁹, and the Clinical Trials Transformation Initiative⁶⁰ both aiming to improve the efficiencies of trial conduct, should also help researchers maximize the efficiencies when conducting clinical trials (see Table 1; 10th recommendation).

To gauge further the researcher community about the series we surveyed them (see Methods panel). Most researchers agreed that the series was important to increase research value. However, basic scientists and clinical researchers had notably different perceptions of the concept of waste in research. For example, some basic scientists disagreed with the concept and believe waste was less important in their field (e.g., "[...] to state that 85% of research funding is wasted is an insult to current research efforts"; "There is no [...] waste in pure, basic science"). Some were concerned by the risk of a negative impact of the series on the societal view of the value of research, which could result in decreased funding. The reluctance of basic researchers to face waste in research in their field contrasts with the evidence of the lack of reproducibility of basic and pre-clinical research. 5,62

Most researchers endorsed the series recommendations. Nevertheless, they identified some barriers to increasing research value (see Table 3). Barriers to protocol registration and data sharing included the fear of inappropriate use of data, issues related to patient confidentiality, the protection of original researchers' efforts, and the risk of having their ideas stolen by others. Some also

considered that adherence to these recommendations could decrease researchers' autonomy and be an obstacle to scientific discovery (e.g., "In basic science, there is a great need for flexibility to modify the protocol in response to the latest finding. Too rigorous control on the planning of experiments would simply kill the last nerve in basic research"; "Research is not a car factory").

Lack of expertise and appropriate support were also important barriers to performing systematic reviews before planning additional studies. Some researchers expressed some concern about the emergence of several quality constraints adding many discrete tasks (e.g., protocol registration, adherence to reporting guidelines, data sharing etc.) that would create a cumulative and discouraging burden for researchers (e.g., "We can't overly restrain creative scientists with organizational rules without burdening their work"). In fact, although adherence to these recommendations should have a positive collective impact for patients and researchers, perhaps researchers should be rewarded for implementing them. Finally, researchers identified important structural factors involved in waste in research such as the top-down funding system with an inappropriate identification of priorities, a questionable peer-review and selection process, the evergrowing "red tape" in research, and a reward system based on quantity of publications and journal impact factor rather than on quality. It is important to take into consideration these barriers and provide appropriate education, incentives, and support to improve researchers' compliance with these guidelines and increase research value. Nevertheless several researchers in the field of basic science have taken the lack of reproducibility and waste in research very seriously and initiatives are already underway to facilitate the implementation of these guidelines.⁶³

The overall response to the 2014 series might be summed up as – some gratifying actions, but much, much more to be done. From a bibliometric and social media perspective, the series has

gained some traction, which is encouraging. Recognition of the problems described in the series, and dialogue about the recommendations, and possible ways to monitor progress are important first steps. However, if we are to avoid the well known problem of failing to implement research knowledge into practice⁶⁴, we will need to use systematically planned knowledge translation strategies including the use of theory-based strategies⁶⁵ to influence research practice, programs, and policies of the five included groups, and others. A good starting point may be to re-visit the series' recommendations and consider ways of monitoring of increased research value (see Table 1).

Across the five groups our investigation has revealed nuggets of innovation and leadership, and indications of potential change, all of which need to be harnessed and sustained. Historically, the stakeholders have venues to talk and act within their own silos, such as the ICMJE for editors and HIRO for funders. However, we are unaware of any venue in which these groups collectively engage to discuss and cross pollinate ideas, or promote better research practice. The paradox is that the problems outlined in the series are large and complex (e.g., there are likely large systemic and cultural differences between preclinical and clinical researchers, and others, such as health services and populations health researchers, in how problematic they see waste or how they think it should be reduced) and no one group is responsible for addressing them. Harnessing research value may be optimized through more collaborative efforts. One immediate venue to help begin the dialogue is the forthcoming REWARD/EQUATOR conference (http://researchwaste.net/research- <u>wasteequator-conference/</u>), envisaged as an annual forum to monitor progress and exchange ideas on improving the entire research system. The structure of the meeting has been set up deliberately to help promote and harness collaboration between all of the sectorial groups, and others, and will specifically include a meeting of several networks interested in improvement of at least one of the 5 stages.

All five targeted groups have a role to play in increasing research value. Some argue that the most effective strategy for maximizing research value may be through the leadership of funders and regulators. Funders can use funding policies to support recommendations in the series and provide guidance to researchers on how to minimize waste. For example, the National Institutes of Health offers training in 'Responsible Conduct of Research' (http://grants.nih.gov/training/responsibleconduct.htm), an emphasis reflected in initiatives of some professional bodies, such as the American Psychological Association (http://apa.org/research/responsible/index.aspx). Funders can also hold back a proportion of grant funding for research that has not yet been made publically available, to bring about better value. Regulators have the authority and enforce change in keeping with the series recommendations. 42 Research ethics boards, for example, could play a greater role in checking that it has been demonstrated that more research in an area is needed and helping to ensure that all relevant studies are appropriately registered (see Table 1; 14th recommendation). Funders can employ strong financial incentives, such as holding back a proportion of grant funding for research that is not published or made publically available, to bring about better value. They can also use funding policies to support the series recommendations and provide guidance to researchers on how to minimize waste.

362

Others argue that academic institutions are ideally placed to lead the movement to enhance research value. They are training subsequent generations of researchers, some of whom migrate to other places of employment, such as journals, funders, and academic institutions For example, perhaps universities could employ a new professional - publications officer - to help researchers, their staff, and trainees. ⁶⁶ Publication officers could also help researchers adhere to policies of funders and journals, such as registering their studies at inception and using reporting guidelines to

report their research. Other innovations could also be integrated into the role of publications officers, including helping researchers when developing research protocols.⁶⁷

384

385

Another strategy that might be considered is setting adherence targets for each of the series' 17 recommendations and monitoring progress towards achieving the targets. Would it be unreasonable to consider annual increases in research value, say by 10% over the next decade? For example, a 2012 survey⁴⁹ of journals' instructions to peer reviewers shows that reference to or recommendations to use reporting guidelines during peer review was rare (19 of 116 journals assessed; 16%). Positive incremental change could be observing at least a 10% improvement in guidance to peer reviewers in the 116 journals initially surveyed. More active dissemination, in keeping with the series recommendations, might involve journal organizations, such as ICMJE and the World Association of Medical Editors, promoting use of reporting guidelines by peer reviewers and authors. This might constitute part of a toolkit for groups affected by reporting research. More generally, increases in research value can cut across stakeholders and dimensions of research (see Table 1). These issues along with a general discussion about infrastructure needed to facilitate and monitor change in research value, and ways to fund it, will be discussed during the forthcoming REWARD/EQUATOR meeting in Edinburgh (http://research-waste.net/research-wasteequatorconference/) which is planned as a series of meetings to bring together funders, editors, and research organisations together with groups working on methods to reduce research waste..

Perhaps it is also time to reconsider how the entire research awards system works? It has been in place for a considerable time and the current state of biomedical research suggests a different set of metrics and currencies may be needed to increase the value of research investment (see Table 1; 12th, 15th, and 17th recommendations). During the waste launch symposium some argued that the current reward system is conservative and not open to new ideas. Alternatives could

be discussed, piloted, evaluated, and, implemented if they bring better research value. ^{68,69} The need for a paradigm shift in the research reward system is also something else that could be discussed at the forthcoming REWARD/EQUATOR meeting.

Our initial observations are based, in part, on examining websites which were often difficult to navigate. Similarly, it is possible that we missed information or that some of the content has been modified since we examined it. For example, on some journal websites 'instructions to authors' are modified at the beginning of the calendar year. The survey response rates were also lower than we would have liked requiring more cautious interpretation.

This overview is a starting point. The plan is to publish more in-depth assessments of several of the stakeholder groups examined and encourage others to do likewise. Several of the issues reported here will be part of the deliberations at the forthcoming REWARD/EQUATOR meeting. The meeting will be a central point for funders, regulators, journals, academic institutions, researchers, and others, to help increase the value of the enormous investments made in biomedical research. We are all responsible for helping to ensure that all research is planned, conducted and reported to such high standards that it is of value to all. Everyone deserves a guarantee of reliable evidence resulting from the global research endeavours.

Contributorship

DM coordinated the project, wrote the first draft of the introduction and discussion, and with IG completed the assessment of the journals, including the editor interviews and initial draft; PG, MN, and IC completed the funders assessment and initial draft; PMMB and DAK completed the academic institutions assessment and draft; and IB and PR completed the researchers (authors) assessment and draft. All authors provided feedback on subsequent drafts of the paper.

| Medical Research Council – MRC (United Kingdom) | For setting the research agenda stakeholder involvement is very important (includes department of health, department of international development, devolved administrations) but they don't get involved in individual funding decisions. In individual funding decisions, strong involvement of researchers and the private sector (pharma industry); very limited and selective involvement of the public and patients. | latter is perhaps not completely clear on the website) No, Expert opinion seems to be the key factor. A lot of MRC funding goes to basic laboratory work. The latter requires clear rationale based on an analysis of previous work but not a systematic review per se The only proposals requiring systematic assessment of existing evidence are global health clinical trials. | systematic review as part of their protocol, must register protocols on the PROSPERO database. Yes for clinical trials. The funding of large scale clinical trials is done through NIHR Efficacy and Mechanism Evaluation (EME) Programme so their requirements which include clinical trial registration are followed. | MRC has policies for data sharing although it emphasizes access for scientists, not the public. The research councils in UK have an overall open access policy and give universities budgets to publish completed research in an open access format, although there is flexibility. | There is no policy on protocols, only a policy for completed research beyond the requirements of sharing information as part of registering clinical trials. | There is an overall strategic plan to guide decisions about research priorities and there are specific goals and objectives for each funding panel. The strategy Board, the Research Boards and the four overview groups (Public Health, Global Health, Translation and Research Careers) are heavily involved in setting the research agenda and identifying priorities. |
|---|---|--|--|---|--|---|
| | Public and patients. Public and patients are only involved in selective projects if deemed appropriate. | | | | | |
| National Health and Medical Research Council - NHMRC (Australia) | Researchers are strongly involved. The degree of involvement of other stakeholders is unclear. | No, Expert opinion seems to be the key. No explicit mention of the need for systematic reviews prior to new primary research. | Yes. For Clinical trials only | Yes. Publication from NHMRC supported research must be deposited into an open access institutional repository within a twelve months of publication but | No. We were unable to identify a policy for access for protocols beyond the requirement to | There is an overall strategic vision and they have health care, preventive and community health and genetic committees to advise them along with clear principles: |

629

Please see PowerPoint slide (Waste initial observations figure 1).

Frequency of responses to 10 questions from websites of 119 core clinical journals included in Medline's Abridged Index Medicus (http://www.nlm.nih.gov/bsd/aim.html).

640 641 642

- Q1 Does journal ITA explicitly mention reporting guidelines (such as CONSORT)?
- Q2 Does journal ITAs explicitly mention the EQUATOR Network?
- Q3 Does journal ITA explicitly mention clinical trial, systematic review, or other registration (such as PROSPERO; indicate which one(s) specifically)?
- Q4 Does the journal ITA mention use of systematic reviews as part of reporting main study results (e.g., item 23 of CONSORT**)?
- Q5 Does the journal's Instruction to Authors recommend authors to go to the ICMJE Website for guidance?
- Q6 Does the journal support publishing "research on research", such as a "methods and reporting section"?
- Q7 Has the journal published editorials highlighting the series, other pieces on waste, duplication, reporting guidelines, registration, other topics related to increasing value?
- Q8 Does the journal provide support for good reporting infrastructure? Ex: study registries, data repositories, other
- Q9 Does the journal mention open access?
- Q10 Does the journal have a policy on public access to data from completed research?
