ABSTRACT

A novel tri-unsaturated C25 highly branched isoprenoid (HBI) alkene has been identified in a laboratory culture of the diatom Navicula salinicola and its structure determined using a combination of NMR spectroscopy and gas chromatography–mass spectrometry (GC–MS). This represents the first report of a C25 HBI in a marine diatom from the Navicula genus, although a different tri-unsaturated C25 HBI has been reported previously in the freshwater species N. siclesvicensis and unspecified HBIs have been identified in the brackish N. phylepta. The newly characterised HBI contains a relatively unusual conjugated diene sub-unit, a structural feature
only previously reported in some HBIs biosynthesised by a further marine diatom, *Haslea ostrearia*.

**Keywords:** highly branched isoprenoid; alkene; diatom; *Navicula salinicola*

### 1. Introduction

C_{25} highly branched isoprenoid (HBI) alkenes are common components of marine and lacustrine sediments worldwide and are biosynthesised by certain diatoms mainly belonging to the genera *Haslea*, *Navicula*, *Rhizosolenia*, *Pleurosagma*, *Berkeleya* and *Pseudosolenia* (Volkman et al., 1994; Belt et al., 1996, 2000, 2001; Sinninghe Damsté et al., 1999; Grossi et al., 2004; Brown et al., 2014; Kaiser et al., 2016). A single tri-unsaturated C_{25} HBI (Structure 6; Fig. 1) has been identified in the freshwater diatom *Navicula sclesvicensis* (Belt et al., 2001), and the mainly brackish species *N. phyllepta* has also been reported as an HBI-producing diatom (Sinninghe Damsté et al., 2004), although no structures were given. In contrast, no HBIs have as yet been reported in any marine species within the *Navicula* genus. Here, we identify a novel tri-unsaturated C_{25} HBI isolated from a laboratory culture of the marine diatom *N. salinicola* and report its structure based on analysis by NMR spectroscopy and gas chromatography–mass spectrometry (GC–MS).

### 2. Experimental

The benthic diatom *N. salinicola* was collected from a coastal marine environment (M. Kulikovskiy, June 2016 at Nha Trang, Vietnam, 12°13'14.5"N 109°12'18.3"E) and kept as strain BTD1 in the Laboratory of
Molecular Taxonomy of Aquatic Plants Institute of Plant Physiology (RAS).

(Further taxonomic information can be found in the Supplementary Information). Initially, *N. salinicola* was cultured at 15 °C, 150 µmol m⁻² s⁻¹ continuous light in small flasks (150ml). Samples were harvested by filtration using MF-Millipore™ membrane filters (25 mm diameter, 0.3 µm pore size) during the exponential and stationary growth phases (Fig. 2).

Large-scale cultures were then set up in several 2 l conical flasks under the same growth conditions. 80 l of such cultures were harvested by centrifugation (4000 rpm, 10 mins) during the stationary growth phase. For the small- and large-scale culture experiments, we used enriched f/2 medium (Guillard and Ryther 1962), along with the following nutrient concentrations: 2646 µM NaNO₃, 318 µM Na₂SiO₃, 108 µM NaH₂PO₄. The filtered and centrifuged biomass was freeze dried and the resulting dry material extracted via sonication using hexane (3 ml (small-scale cultures); 25 ml (large-scale culture)). The total hexane extract (THE) was then concentrated by removing hexane under a stream of nitrogen and partially purified using column chromatography (SiO₂). The hydrocarbon fraction (hexane) was analysed by GC–MS using an Agilent 7890 gas chromatograph equipped with a HP₅MS fused-silica column (30 m; 0.25 µm film thickness; 0.25 mm internal diameter) coupled to an Agilent 5975 series Mass Selective Detector (MSD). NMR data were obtained using a JEOL ECP-400 NMR spectrometer with chemical shifts measured relative to those of CDCl₃ (¹H: 7.24 ppm; ¹³C: 77.0 ppm). NMR data were collected on the THE
obtained from the large-scale culture. The purity of the newly reported C\textsubscript{25:3} HBI (see Section 3) in this THE was estimated to be ca. 90\% based on its relative peak area (GC–MS; Supplementary Information) and by the relative integration values of H-23 (Fig. 1) versus the alkenic protons of the co-occurring polyunsaturated linear alkenes (δ = ca. 5.3 ppm) in the \textsuperscript{1}H NMR spectrum.

3. Results and discussion

Following extraction of several small-scale cultures of \textit{N. salinicola} from the exponential and stationary growth phases, analysis of partially purified THEs by GC–MS revealed the presence of a suite of closely eluting polyunsaturated linear alkenes (e.g. heneicosa-3,6,9,12,15,18-hexaene; \textit{n}–\textit{C}_{21:6}), trace amounts of a di-unsaturated HBI (2; Fig. 1) and a further compound exhibiting similar mass spectral properties to a range of C\textsubscript{25} HBIs characterised previously. However, although the retention index (RI) of this component (RI\textsubscript{HP5ms} = 2141) did not match that of any previously reported C\textsubscript{25} HBIs, hydrogenation of an aliquot of one THE resulted in the formation of the parent HBI alkane C\textsubscript{25:0}, thus confirming the C\textsubscript{25} carbon skeleton.

Interestingly, this new HBI was only detected in cultures harvested during the stationary phase and was identified as tri-unsaturated on the basis of its molecular ion (M\textsuperscript{+} 346; Fig. 3). At this point, it is not clear why this new HBI and the co-occurring diene 2 were not detected during the exponential growth phase, although we note that some variability in cellular HBI concentrations and distributions have been reported in a small number of
previous studies (e.g. Wraige et al., 1997, 1998, 1999; Brown et al., 2020).

From the large-scale culture of *N. salinicola*, we obtained ca 0.2 mg of the partially purified HBI triene (3; Fig. 1), which enabled full structural characterisation using $^1$H and $^{13}$C NMR spectroscopy. A conjugated diene sub-structure (C22–C25; C23–C24; Fig 1) could be readily identified through a particularly characteristic low field resonance in the $^1$H NMR spectrum due to H-23 (Wraige et al., 1997; Allard et al., 2001), together with further low field resonances that could be attributed to alkenic methylene protons at C24 and C25 (Table 1). The third double bond could also be identified from its methylene protons at C17. Alternative positions for this third double bond at C1–C2 or C14–C15 can be discounted due to the observation of two isopropyl groups in the $^1$H and $^{13}$C NMR spectra (Table 1). Further, a double bond at C10–C18 leaves a solitary methyl group at C17 whose $^{13}$C chemical shift would be at ca. 15.5 ppm, by comparison with related compounds (e.g. 1; Belt et al., 2012). In contrast, isolated methyl groups at C18 in previously characterised HBIs resonate at ca. 19–20 ppm (e.g. 19.8 ppm for HBIs 1 and 2; Fig. 1) (Johns et al., 1999; Belt et al., 2012), consistent with that observed for HBI 3 (i.e. 19.9 ppm; Table 1). The $^{13}$C NMR spectrum of HBI 3 also contained individual resonances due to the six magnetically inequivalent alkenic carbon nuclei (Table 1) and complete $^{13}$C resonance assignments could be proposed by comparison with structurally similar HBIs characterised previously (Fig. 1; Belt et al., 1996, 2012; Wraige et al., 1997; Allard et al., 2001), some of which contain a conjugated diene.
sub-unit (i.e. 7–8). The GC RI of HBI 3 (RI_{HP5ms} = 2141) is substantially higher than those of some other HBI trienes (e.g. RI_{HP5ms} = 2114 (4); 2109 (5); 2090 (6)) but is consistent with that reported for the structurally related tetraene 7 (RI_{HP,5} = 2159; Allard et al., 2001).

The identification of a C_{25} HBI in *N. salinicola* represents the first example of HBI production within a marine *Navicula* species despite the near-ubiquity of this genus within natural diatom populations. Since the *Navicula* and *Haslea* genera are quite similar, phylogenetically, with the latter well-known as an HBI-producing genus, the new finding is probably not surprising; however *Navicula* is a far more common genus, potentially making it a more important source of some HBIs in marine sediments. In terms of its structure, the conjugated diene sub-structure (C_{22}–C_{25}; C_{23}–C_{24}; Fig. 1) is somewhat unusual, although there is some previous precedent for such a feature in other HBIs isolated from a small number of cultures of the marine diatom *Haslea ostrearia* (Wraige et al., 1997; Allard et al., 2001). In fact, HBI 3 is a close structural analogue of HBI 7 identified previously in *H. ostrearia*, albeit as a minor component. Since the retention index of HBI 3 (RI_{HP5ms} = 2141) is similar to two HBI tetraenes identified in some cultures of *H. ostrearia* (*viz.* RI_{HP,5} = 2143–2146; Allard et al., 2001), one of which also contained HBI 7, it possible that HBI 3 may also have been present in the corresponding lipid extracts, but not identified due to co-elution. We are unaware of any geochemical reports of HBI 3 although its characterisation described herein may, in the future, lead to its positive
identification in sedimentary archives, an outcome that may potentially add
to the use of HBIs as palaeoenvironmental indicators (c.f. HBIs 1 and 2 for
Arctic and Antarctic sea ice; see Belt, 2018 for a review).

4. Conclusions

We report the structural identification of a novel C_{25} HBI biomarker
in the marine diatom *N. salinicola*, the first example of HBI production
within a marine *Navicula* species, thus expanding the potential number of
sources of HBIs in the environment. Further studies into *N. salinicola* and
related species may prove valuable in the use of HBIs as
palaeoenvironmental proxies.
